56.5 The Psychiatric Hospitalist

ANGEL CIENFUEGOS, M.D.

The “psychiatric hospitalist” model has been adopted for over a quarter of a century by the American healthcare delivery system and other systems around the world. As opposed to the nonhospitalist traditional models, these are medical providers who are part of inpatient programs in medicine, pediatrics, surgery, and now mental health in which the medical care is provided. The hospitalist is a specialist in inpatient treatment based in an inpatient facility or hospital. This type of practice specializes in acute and serious illness rather than chronic ambulatory medicine and health maintenance. They are knowledgeable about comorbidities in acute and critical clinical presentations. The number of hospitalists has grown consistently, and it has been suggested that the generalist who cares for patients across the full continuum of care may be a vanishing breed.

Traditionally, patients had been cared for in the hospital by their prior primary care physicians, in most cases family practitioners or general internists in a “Continuity of Care” model. Over the past several years, hospitalized patients’ care is now more likely to be provided by a hospitalist. In especially complex cases that require multiple consultations with subspecialists, it is the hospitalist who coordinates care. When the patient is discharged, they return to the care of the primary care physician and routine follow-up by other medical specialties. This change parallels the change of practice patterns in psychiatry, in which, in many instances, a separate psychiatrist may care for a patient while admitted for inpatient treatment. Historically, these individuals in psychiatry have been called unit directors or ward chiefs of large state mental institutions. However, in their current role, they are the psychiatric parallel of the hospitalist found in medicine and pediatrics. In both cases, outpatient physicians relinquish the care of hospitalized patients to inpatient specialists.

The development of the hospitalist model has occurred similarly for medicine and psychiatry in the context of the changing role of acute care hospitals. As both medicine and psychiatry become more ambulatory in orientation, inpatient institutions have moved away from their central role in health care. They have become specialized institutions for acutely ill patients. Generally, the level of severity of illness in the inpatient setting has continued to increase as well as the number of comorbidities. Although the hospitalist model was widely accepted previously in Canada and the United Kingdom, the first modern hospitalist program was established in the United States in 1994, overcoming the opposition of many primary care physicians who objected to the model because of the disruption in continuity of care. In any case, it was a fact that inpatient care had become an economically inefficient use of their time.

The hospitalist has emerged in response to the increasing complexity of care associated with hospitalized patients. These individuals, with time and training, develop significant experience with acutely ill patients. They develop an understanding of continuity and coordination of care since part of their responsibility is to work on the "hand-off"—the patient's transition from outpatient to inpatient and, after treatment, back again to the prior outpatient physician.

The initial growth in the number of hospitalists occurred because leaders at health maintenance organizations (HMOs), some hospitals, and medical groups believed that they would lead to a reduction in inpatient costs without a reduction in patient satisfaction or quality of care. Reduced residency work hours contributed to the growth of hospitalists as hospitals' need for more on-site physicians grew. Recent estimates indicate that the current number of hospitalists in the United States is nearly 30,000. In 2010, 57% of U.S. hospitals had hospitalists on staff, including 87% of hospitals with a number of beds equal to or above 200. Around 80% of VA hospitals currently have hospitalists. Membership of the professional organization for hospitalists, the Society of Hospital Medicine, is about 6,000.

Because hospitalists have become common at the major teaching hospitals in the United States, they have also become a major provider of instruction to medical students and residents in internal medicine and pediatrics. These two groups now receive much of their inpatient education from hospitalists working in their role as attending physicians.

THE DEFINITION OF HOSPITALIST PHYSICIANS

Hospitalists are defined as physicians who have general inpatient care as the primary focus of their professional activities, which include clinical care, teaching, research, or administration. Hospitalists typically spend more than 25% of their time working in hospital settings. Commonly they are internists taking the place of primary care physicians in providing inpatient care. In addition to patient care responsibilities, many hospitalists become involved in clinical-administrative tasks. Commonly these include quality improvement efforts and peer review. Academic hospitalists may explore issues such as outcomes research that explores the cost and quality of inpatient care. Many lead the development of new inpatient educational programs for house staff and medical students. Most hospitalists work in community hospitals; a smaller number work in teaching hospitals. In those academic settings, their responsibilities expand to include teaching medical students and residents.

In general medicine, most hospitalists have been trained as internists. There is no separate training program for hospitalists, although some residency tracks and 1-year fellowships have begun to emerge. Such residency tracks typically focus on training in inpatient medicine in addition to hospital-oriented quality improvement, patient safety, and end-of-life care. Fellowships usually focus on providing future academic hospitalists with the research skills they will need in areas related to inpatient care.

Hospitalists are usually salaried physicians with defined work hours. They care for patients with complex medical illnesses rather than the chronicity found in outpatient practice. Many of them have interests in health systems and want a chance to improve the quality of services and control costs associated with inpatient practice. The increasing complexity of medical care demands greater specialization. In many settings, it is increasingly regarded as unrealistic to expect physicians to have expertise in both inpatient and outpatient medicine. Supporters of the hospitalist movement emphasize the benefits of a specialized knowledge base. Hospitalists specialize in inpatient care, allowing primary care physicians to focus on ambulatory care. A consequence of the increase in the number of hospitalists has been a proportionate increase in the number of “office-only” physicians as well.

Hospitalists in academic settings are on-site experienced physicians. Their presence helps hospital wards to run more smoothly and, by doing so, increases patient and nursing staff satisfaction. Such individuals are usually familiar with the ward dynamics. They also usually have a good relationship with the ancillary staff, appreciate their contributions, and have long-term commitments to the hospital. Such involvement facilitates the management of clinical situations to prevent them from evolving into significant problems. Such individuals also usually have a breadth of clinical knowledge and experience from working in hospitals and are skillful in the expeditious treatment of the seriously ill, comfortable in managing multiple minor inpatient problems, and familiar with consulting various medical and surgical specialists. These attending physicians are also best positioned to provide the supervision that interns and residents need when managing acutely ill inpatients. Due to their inexperience and rapid turnover, interns and residents benefit from the support that a responsible physician provides when making major medical decisions.

It has been suggested that the minimum amount of inpatient work expected of a hospitalist is 25% of their practice. This minimal amount allows the hospitalist to become experienced in the management of common inpatient conditions. Relationships with care providers in affiliated disciplines can also develop more easily with this degree of availability. Such individuals are also more likely to become committed to improving the hospital by participating in quality improvement efforts and helping to control costs.

There are two common models of hospitalist care. The most common consists of full-time inpatient physicians who practice as a group. In the second model, a group of physicians rotate responsibility for inpatient care. The rotational periods vary, depending on the practice of the group. This method allows a group to maintain skills in both inpatient and outpatient practice. It can, however, produce frequent periods of discontinuity in outpatient care.

An additional aspect of the hospitalist model is whether it is voluntary or involuntary. In some managed care organizations, the outpatient physician is required to transfer care to a hospitalist when the patient is admitted for inpatient treatment. Commonly under this model, the outpatient physician is not permitted to write orders and is relegated to visiting the patient in the hospital. In contrast, many physicians voluntarily transfer responsibility for the care of their patients to hospitalists, cardiologists, or specialists in intensive care medicine. For example, it is common for primary care physicians to transfer care of their patients to intensivists (physicians specializing in intensive care) when their patient is admitted to the intensive care unit (ICU). In a similar manner, geriatricians working in nursing homes commonly transfer care to internists when their patients are admitted to the hospital. Although not all hospitalists may have the same degree of interest or ability in studying patient outcomes or developing practice guidelines, most of them participate in these creative activities.

ROLES OF THE HOSPITALIST

The predominant role of the hospitalist is to take care of hospitalized patients. Over the years, inpatient care has become more complex and specialized, and while the number of hospitalized patients has decreased, the acuteness of their conditions has risen. Simultaneously, the scrutiny of the length of stay (LOS) and associated hospital costs has increased. It is common to see hospitalists involved in projects to reduce the LOS and cost of admission. Generally, reports show that inpatient care of medical patients by hospitalists reduces LOS and hospital costs. Hospitalists are able to respond rapidly to changes in a patient’s condition because they tend to be readily available and are able to expedite the timing of treatments and consultations.

The hospitalist is also the receptor for inpatient admissions. Increasingly, outpatient physicians prefer to transfer hospital care to a specialist. Common reasons for this preference include the convenience of uninterrupted outpatient work, the convenience of not making rounds in the hospital, and a lack of expertise or comfort with the acuteness of illness and clinical skills associated with inpatient work. There is also some desire to avoid the intensive scrutiny associated with providing care to hospitalized patients. Similarly, hospitalists provide pre- and postoperative medical care to surgical patients. Their availability allows the surgeon to be in the operating room all day and ensures that the patient receives appropriate medical care. Many health care systems are having hospitalists become the physician of record for nonmedical inpatients with medical comorbidities.

An analogous situation has long existed with ICUs. Most ICUs are closed, meaning that they use dedicated critical care physicians who accept the patient from the generalist on the ward and transfer care back to them when the patient leaves the unit. These physicians have the skills, abilities, and availability to care for critically ill patients, and because of these skills, they have improved outcomes and efficiencies.

In many specialties, including critical care, oncology, bone marrow transplantation, cardiology, infectious diseases, and psychiatry, the hospitalist model is common. The attending physician is dedicated to the inpatient service. In academic centers, this may be for multiple rotations throughout the year or full-time.

An additional role for hospitalists is providing physician participation in hospital management. Commonly this occurs by their joining in quality management operations, the development of hospital policies and procedures, management of the formulary, participation in credentialing activities, and utilization management.

When considering the role of hospitalists, it is useful to realize that they also care for outpatients, often in a consultative role. Some hospitalists participate in follow-up clinics in which patients are seen once or twice following discharge. Such outpatient activities, however, represent only a small fraction of their time.

Hospitalists also play a role in communication. Most systems expect the hospitalist or their designee to contact the primary care physician within 24 hours of admission and to ensure that either a summary letter or the discharge summary is sent to the outpatient clinician at discharge.

Another key role for hospitalists in communication is in the transmission of clinical information from the outpatient care physician to the inpatient provider on hospitalization and the subsequent transfer of information back to the outpatient care physician by the hospitalist on discharge. This “hand-off” is symbolic of the transfer of clinical responsibility that occurs during hospitalization. The hospital-based physician assumes responsibility for diagnosis and management. For this reason, most hospitalists believe that there is an obligation to validate the diagnosis. This is, in essence, the provision of a second opinion about the diagnosis and subsequent management. Much has been written about the hand-off. It is one of the two controversies of the model (the other controversy being the obligatory use of hospitalists). The disadvantage of the hand-off is obvious: important information can be lost and result in discontinuity. There may also be patient dissatisfaction because of the assignment of a new physician.

The hand-off can also be viewed as producing one of the strengths of the hospitalist model. It results in the patient being under the care of a physician in the hospital throughout the day. This individual reacts to clinical data in real time. They are the coordinators of inpatient care. However, some surveys show that patients are at least as satisfied with the care from hospitalists as they are with care from their primary care physician. The data suggest that patients may be willing to trade familiarity for availability. It is also noteworthy that many hospitalized patients do not have primary care physicians, especially among the uninsured. In some systems, when hospitalists are introduced, there is an increase in patient satisfaction with their outpatient physician, suggesting that the improved ability to focus on their outpatients is a benefit of this model for the primary care physician.

Hospitalist systems that focus on inpatient–outpatient communication have fewer difficulties. Commonly, programs fax the discharge summary to the outpatient clinician on the day of discharge. Some programs fax daily progress notes as well. Increasingly, programs have a continuity clinic in which patients may be seen once or twice soon after discharge to ensure stability before the patient reappears at the primary care physician’s office.

THE PSYCHIATRIC HOSPITALIST

It could be argued that psychiatry was the first of the medical disciplines to adopt the hospitalist model on a large scale. Of interest, however, full-time inpatient psychiatrists have never called themselves hospitalists. Psychiatric hospitals and asylums date back to the early Middle Ages. Until the rise of psychoanalysis, the most widely available career opportunity available to doctors treating the mentally ill was working in a hospital. The choice of career was to work in a publicly supported state mental hospital or a private psychiatric hospital. The physicians then resembled what we would consider to be hospitalists.

In the twentieth century, the advent of antipsychotic drugs led to the trend of deinstitutionalization. Psychiatry, together with numerous other disciplines, adopted the model of continuity of care, in which physicians follow their ambulatory patients in outpatient settings and while hospitalized in the event of a needed inpatient stay.

As the field has expanded and the effect of third-party payers has restructured the profession, the proportion of hospitalists has declined while the absolute number has increased. One of the earliest surveys of career areas for psychiatrists dates to 1953; it noted the role of psychiatrists working full-time in hospitals. Later surveys noted that the percentage of psychiatrists working in mental hospitals was decreasing. In 1965, for example, about 30% of psychiatrists worked in hospitals, but by 1979 this had dropped to less than 14%.

One of the problems that nonhospitalist-based psychiatrists encountered was that admitting and caring for hospitalized patients was very disruptive to their careers as outpatient clinicians, academicians, teachers, and researchers. The role of unit director or ward director has been a traditional role in psychiatry. At one time, these individuals were relatively junior psychiatrists who, in academic settings, attempted to succeed in the traditional “triple threat” role. That is, they pursued success in research, patient care, and teaching. In any setting, academic or not, these individuals are the epitome of the psychiatric hospitalist. Their job functions are highly congruent with the descriptions of hospitalists noted earlier.

In 2010, a hospital part of the Veterans Affairs Healthcare System transitioned its mental health inpatient units from nonhospitalist or continuity of care (nonhospitalist based) to a hospitalist-based model of care. This change resulted in an increase in the total number of discharges and a decrease in the number of readmissions within 30 days. Patients discharged by hospitalists were more likely to follow up with after-care appointments.

From a financial standpoint, psychiatric healthcare delivered by hospitalists decreases the LOS and the cost. It also facilitates the care of patients with medical comorbidities since medical consults are readily available, and hospitalists can easily coordinate care with hospitals’ medical and surgical disciplines. In turn, psychiatric hospitalists provide psychiatric consultation to medical and surgical units, reducing those specialties’ cost of care.

Psychiatric hospitalists are familiar with the assessment and treatment of the most severely mentally ill patients, including patients with acute psychotic agitation and patients who attempt to harm themselves or others. They manage patients whose psychiatric illnesses put them in physical danger, such as patients who are suicidal or engage in self-injurious behaviors. They are comfortable with protocols to manage delirium and to assess and treat withdrawal from alcohol and other substances.

Psychiatric hospitalists also have extensive training in the legal requirements for involuntary detention and involuntary medication administration, and they frequently testify in judicial evidentiary hearings. Civil commitment statutes vary across states, and psychiatric hospitalists are familiar with the statutes for their state, including the requirement for civil commitment hearings within a specified time and the rights of the detained person. For example, some states give detained patients the right to refuse treatment, while others do not. Psychiatric emergency hold laws vary in length from 23 hours to 10 days across the United States, and psychiatric hospitalists know the criteria that must be met for the initial emergency hold and for psychiatric holds to be extended. Psychiatric hospitalists spend most of their time in inpatient units. They carry a significant share of resident and medical student training. Trainees working with hospitalists are frequently more satisfied with the amount of time and dedication they get from their attendings, which normally are part of the clinical faculty of the associated academic institution. These faculty members are expected to be educators in addition to clinicians and are not subjected to the same publication and funding expectations of research faculty. The inpatient units are the center for education and training during the first years of residency and offer the appropriate diversity of clinical presentations providing students with the appropriate amount of learning material.

Psychiatric inpatient units are environments where multidisciplinary approaches involving psychiatrists, nurses, psychologists, social workers, caseworkers, substance use counselors, and, as needed, medical consultants from other medical disciplines. Due to the multidisciplinary nature of inpatient hospital work, psychiatric hospitalists are able to treat medical comorbidities more effectively and are well-qualified to assess appropriateness of transfers from medical to psychiatric units.

HISTORY OF THE MODERN HOSPITALIST MOVEMENT

Several factors have led to this practice pattern. For outpatient clinicians, the arrangement frees them from the disruptive burden of seeing a small number of inpatients. It allows them to focus on their area of expertise: outpatient practice. It avoids the disruptions in the outpatient schedule that can occur when inpatient rounds are a daily responsibility. For the hospital and third-party payers, the model reduces inpatient expenditures with similar clinical outcomes. This model does not adversely affect patient satisfaction with care or trainees' satisfaction with their educational experience. Although this practice pattern may benefit hospitals or group practices, its professional fees are not usually sufficient to make the program self-supporting. To remain viable over the long term, such programs require support from the programs such as hospitals or group practices that receive benefit from the efficiencies that these programs produce.

The traditional model for inpatient care was outpatient physicians who made hospital rounds early in the morning and again at the end of the day. There could be calls from the emergency room or the hospital. The calls would, at times, interrupt outpatient practice and interfere with the efficient treatment of outpatients. Many clinicians noted a decline in office productivity when they were obliged to make hospital rounds for a small number of inpatients.

A significant factor that led to the development of hospitalists was the desire to focus efficiently on outpatient treatment and allow inpatient treatment to be provided by those who would give it full-time attention. This allows outpatient physicians to avoid the frequent interruptions, paperwork, and preauthorizations associated with inpatient care.

The acuteness and diagnostic complexity of inpatients have been increasing for the last several decades. At the same time, new and more complex treatment modalities have emerged in inpatient care. Those who only infrequently care for inpatients have found it increasingly difficult to remain current in these treatment methods. Part of the appeal of the hospitalist movement has been that it frees outpatient physicians from the responsibility to remain current with treatments they would only rarely use.

In England and Canada, the early recognition of the benefits of focusing on either ambulatory or inpatient care led very early in this process to the concept of distinct outpatient and inpatient physicians. The term "hospitalist" was first used in the United States by Wachter and Goldman to describe the concept.

In academic medical centers, hospitalists have become a third career pathway in addition to the prior pathways of clinical educator and clinical researcher. The development of the clinical educator had been due to the need to care for outpatients and to teach students and residents at ambulatory care sites. How an individual physician spends their time is highly variable and tends to depend on the needs of the institution and the skills and experience of the individual physician. Time is typically divided among providing direct care to outpatients, supervising students and residents in providing ambulatory care, and various scholarly activities. Many also spend several months each year attending an inpatient unit, during which time outpatient responsibilities are reduced. Educational activities may include responsibility for specific courses in the medical school curriculum or the teaching of specific knowledge or skills, for example, the patient examination. Most academic medical centers expect their clinician teachers to do scholarly work to meet standards for promotion. These activities commonly include developing new educational programs, writing review articles or case reports, conducting research, and presenting original work at scientific meetings.

In Europe and Canada, there have long been specialists in inpatient general medicine who have been active in urban hospitals. A clear demarcation between inpatient and outpatient practice is new in the United States. In the United Kingdom, the consultant physician would take over care from the general practitioner when the patient was admitted to the hospital.

The increasing use of such hospitalists was initially spurred on by the emphasis on efficiency that came with the rise of managed care. The managed care environment stimulated the development of the hospitalist model in the United States. The emphasis on efficiency and cost containment took precedence over continuity of care.

Up to the 1970s, most primary care was provided by a general practice physician who was not board-certified in any particular specialty. Most medical care at that time was provided in a hospital setting. In the inpatient setting, the general practitioner was often assisted by the internist, who was often more experienced in inpatient medicine. By the 1980s, family practice had emerged as a specialty and came to define the general practitioner. The role of the internist in inpatient practice was diluted by the rise of medical specialists who could assist the general practitioner with inpatient care. Until the mid-1990s, hospitalists were uncommon in general medicine in the United States. Rare examples of hospitalists in the United States before the 1990s were called house doctors, hospital rounders, or inpatient managers. By the 1990s, however, general internists and family practitioners had begun to focus on outpatient care and had a progressively smaller role in inpatient care.

Internists began to manage inpatients, and intensivists emerged to manage ICUs. Emergency departments began to be staffed by specialists in emergency medicine.

Although multiple forces were responsible for this change, two major factors were predominant—cost pressures on hospitals and physicians and the increasing acuteness of inpatients. The shift of most medical care to the ambulatory setting resulted in most physicians having little ongoing experience with inpatient care. Practice effects meant that those who did large volumes of inpatient care had superior outcomes.

Many felt that the hospitalist model conflicted with the traditional notion of a generalist who would treat patients in both inpatient and outpatient settings and, in so doing, provide treatment that was less fragmented and more holistic.

THE STAGES OF HOSPITAL CARE

It has been suggested that hospital care in the United States has gone through four stages. In the first stage, all inpatients were cared for by their primary care physicians. This worked best when the acuteness of illness was low, most practitioners had large numbers of inpatients, the cost was not as important as it is today, and hospitals were adjacent to practitioners' offices.

The second stage occurred when these conditions no longer existed. Specifically, hospitals are no longer nearby, the acuteness of inpatients is significant, costs are managed, and inpatient care has a significantly higher degree of complexity. Furthermore, outpatient offices are busy due to the shift of care from inpatient to ambulatory. At this point, physicians may form a group to rotate responsibilities for inpatient care. This system introduces an inpatient–outpatient discontinuity. The compensation for this is the enhanced availability of the inpatient physician.

A third stage is the development of voluntary hospitalists who are dedicated inpatient physicians paid by the hospital, medical group, or managed care company. Under this model, not all inpatient care is provided by hospitalists. Primary care physicians retain the opportunity to manage their patients when they are admitted to the hospital.

A fourth stage is the mandatory hospitalist stage. At this point, all inpatients are cared for by hospitalists. This model is most common when there is strong institutional control of physicians. When there is a loose affiliation between the hospital and primary care providers, the relationship is more likely to be at stage three if outside physicians wish to retain control of their patients.

BENEFITS FROM THE USE OF HOSPITALISTS

Many studies of hospitalists have demonstrated a reduction in the cost of care without a change in the quality of care. Hospitalists are more efficient at hospital resource utilization than physicians who spend the majority of their time practicing in ambulatory settings. Many factors are believed to contribute to the improved efficiency of hospitalists. These include the practice effect of being familiar with common inpatient conditions and being more familiar with the hospital system. They are also more available to acutely ill patients and may respond more promptly to changes in their clinical state or changes in laboratory data. Through a rotating on-call system, a hospitalist is on-site at the hospital at all times.

Ambulatory care physicians experience a significant benefit from the presence of hospitalists. Hospitalists allow outpatient-based clinicians to attend to their patients without the disruption in their schedules that can result from the unpredictable demands associated with caring for acutely ill patients in the hospital. Furthermore, many ambulatory care-based clinicians may lack the familiarity with the inpatient management techniques that they had when they were trainees.

For the typical internist, the inpatient census is small. However, this small number of patients typically requires more effort than in the past because the patients tend to be more acutely ill and their care more complex. The pace of hospital work has also quickened, and physicians are under pressure to minimize the LOS. Adding to these challenges is the fact that many conditions that were once an indication for inpatient admission are now commonly treated in the outpatient setting, whether that be the office, the home, or the nursing home. The result is that outpatient practice is also more acute and busier, making the disruptions of providing care for some inpatients also more challenging.

Because most primary care physicians spend decreasing amounts of time caring for inpatients, many feel they have lost some of their skills in inpatient care. This reduction has occurred both because fewer patients are admitted and because the LOS is shorter than in past decades. With fewer inpatients, there are fewer interruptions in a tightly scheduled day of outpatients. What emerges is an increasing split between inpatient and outpatient practice.

Hospitalists reduce inpatient resource utilization, resulting in a shorter LOS and a lower cost of inpatient care without a reduction in quality of care or patient satisfaction. The reduction in resource utilization probably is a practice effect combined with the ready availability of hospitalists for diagnostic and management decisions.

The rapid increase in the number of hospitalists in the United States suggests that there are significant benefits to this position. In terms of patient care, their presence in the hospital and ability to be available on short notice allows patients to be managed rapidly. Their availability permits them to assess patients frequently and to promptly follow up on test results. This is thought to be one of the significant factors in how hospitalist care produces a reduction in LOS. Hospitalists may also shorten a patient's stay in the emergency department by being available throughout the day to admit a patient. An experienced hospitalist usually becomes comfortable caring for acutely ill patients with a variety of medical conditions. In some cases, this may result in a decreased use of laboratory studies and consultative services. This may also contribute to a reduction in the cost of inpatient care.

There are a large number of uninsured patients in the United States. When they present in the emergency department seeking admission, there usually is no primary care physician with whom they have a prior relationship. Therefore there is no outpatient physician available to manage their inpatient care. An increasing role for hospitalists is to provide care for these patients.

An additional benefit of the hospitalist approach is the ability of outpatient physicians to dedicate themselves to outpatient care without the distractions and interruptions of acute inpatients. Many office-based physicians feel that providing inpatient care is not cost-effective. The poor reimbursement for hospital visits is a common reason that many no longer provide hospital care. Outpatient physicians are also increasingly seeing sicker patients. Their volume of inpatient work has also increased. Due to these factors, many physicians feel that it is increasingly important to focus on improving their availability and skills in ambulatory medicine. These goals are facilitated by focusing exclusively on outpatient medicine. Inpatient medical care is increasingly complex. Due to this increasing complexity, inpatient care requires a higher degree of specialization than in the past. For this reason, it is increasingly difficult for physicians with limited inpatient practices to maintain their expertise in inpatient care. Good communication between inpatient and outpatient physicians also has enhanced the acceptance and perception of the benefits of this model. A key aspect of communication is the prompt delivery of a discharge summary to the outpatient physician.

In all areas of medicine, there has been a shift away from relatively healthy individuals with acute illness being admitted to the hospital toward individuals with increasing levels of medical complexity. The hospitalist is increasingly seen as the specialist focused on the medically complex inpatient. Due to their training and experience, these inpatient physicians become proficient in the efficient management of acute illness. Commonly patients are hospitalized because they are profoundly ill or suffer from a rare or atypical illness. They benefit from their hospitalist's inpatient skills.

Hospitalists also work with surgeons to provide primary inpatient care to surgical patients in the pre- and postoperative periods. These combined hospitalist–surgeon teams have been associated with reductions in postoperative complication rates with no significant difference in cost or LOS.

Hospitalists improve the efficiency of inpatient care while maintaining or enhancing the quality of care. Their expertise comes from familiarity with the management of common inpatient conditions. Efficiency consists of reductions in resource use, usually measured as the average LOS and hospital cost. This occurs because hospitalists are familiar with clinical pathways, are experienced in the planning of postdischarge care, and are available throughout the day to respond to changes in diagnostic data or clinical conditions.

Hospitalists relieve office-based physicians of the unpredictable demands of hospital practice. Patients are no longer kept waiting, and physicians no longer have the inconvenience of recurrent trips to the hospital. Outpatient physician productivity increases following the removal of inpatient responsibilities. Outpatient physicians are more reliably available. They are not interrupted by hospital calls or the need to abruptly leave to see acute inpatients. They are able to expand their outpatient hours because they no longer make inpatient rounds. Their workday is more predictable.

Hospitalists standardize the quality of inpatient care. In many academic medical centers, there has been a concern about the wide variation in inpatient abilities found in community-based clinicians. Many programs have worried about granting these physicians admitting privileges or opportunities to participate in the teaching service. When a hospitalist system is used, it allows both the community-based physicians and the outpatient academic faculty to enjoy the same quality of inpatient care that is provided by hospitalist faculty.

Hospitalists produce clinical science with an emphasis on outcomes research, quality assessment, and quality improvement; clinical trials to improve treatment or diagnosis; and the development of clinical guides and pathways.

There is a positive correlation between experience and quality of care in a number of areas of medicine and surgery. When implemented, the hospitalist model has resulted in fewer but more appropriate specialty consultations, lengths of stay, and hospital costs. From familiarity, hospitalists develop good working relationships with ancillary hospital staff, including discharge planners, nurses, consulting specialists, and outpatient physicians. Retention and recruitment improve in the hospitalist system.

HOSPITALISTS AS CLINICIAN-EDUCATORS

Large academic institutions are the leaders in hospitalist-based care. In these institutions, one of the hospitalist functions is the training of residents and medical students. Some are considering or implementing hospitalist fellowships. This means house staff receive training from those with expertise in hospital care. There is an expert readily available throughout the day to confer with about patient management. There is improved teaching and expert guidance. Hospitalists provide role modeling to trainees for careers in hospital work.

The effect of hospitalists on academic medical centers may further the separation between researchers and clinicians. The researchers will further focus on research and obtaining grants. The clinician-educators will concentrate on clinical work and teaching. With the group of clinician-educators, there will be a further subdivision, with some focusing on outpatients and others on inpatients.

Hospitalists also improve the educational experience for medical students and house staff. Because the faculty supervisors are skilled and experienced in modern inpatient care, they provide more effective teaching and oversight. Generally, when academic programs have evaluated the teaching abilities of hospitalists, there has been enhanced satisfaction by students and residents when compared to prior models. Some trainees have also noted a reduction in workload associated with the hospitalist model. House staff report that hospitalists are more effective at teaching than general psychiatrists.

Many academic medical centers have hired hospitalists as clinician-educators. This need has arisen because primary care physicians are able to spend very little time in the hospital. This results in less time with trainees for educational activities. The expectation is that hospitalists will devote more time to education, performance feedback, and supervision.

Resident evaluations of teaching by hospitalists are higher than those of traditional attendings who briefly rotate onto the teaching service.

Clinical research done by hospitalists has traditionally consisted of studying the hospitalist movement. This included studies of the efficiency, cost, and quality of hospitalist-run services, including inpatient–outpatient communication. Research has begun to expand to include prevention of nosocomial infections and hospital quality assessment, including medical error and pain management, health services and outcomes research, and ethics. Newer areas also include clinical trials that focus on conditions common to the hospital and genetic epidemiology.

DISADVANTAGES AND OBJECTIONS TO THE HOSPITALIST MODEL

There are two potential models for the hospitalist system: Voluntary and closed. In a closed system, only hospitalists have admitting privileges, and ambulatory care physicians are excluded. An open system allows both groups to admit their patients. Concerns have been raised that a closed system may engender bad feelings among community physicians.

A potential disadvantage of the hospitalist model is that outpatient physicians will lose their skills in treating inpatients (although some have questioned how serious a disadvantage this may be if they are no longer providing inpatient care). It is clear, however, that by focusing on outpatient care, they can be expected to improve their skills in that area.

Subspecialist consultants may be apprehensive that hospitalists, due to their familiarity with common inpatient conditions, may produce fewer consultations. A reduction in consultations would be associated with a lower cost of care. Because of the severity of illness in hospitalized inpatients, consultations will continue to occur.

During the transition from outpatient to inpatient and again with the transition back to outpatient status, there is a risk of poor communication between the treating clinician and the receiving clinician. With appropriate phone calls and copies of discharge summaries and letters, it is possible to minimize this problem and avoid a significant loss of medical information. An aspect of this coordination of information flow is the risk of fragmentation of care and the loss of a care coordinator who has comprehensive knowledge about the patient’s health. In addition, the discontinuity of care and associated lapses in information flow may be associated with a higher risk of medical error.

An additional issue is that the number of acute care hospitals is diminishing, and with them, so is the relative percentage of patients admitted to the hospital.

Implementation of the hospitalist model has an effect on the roles of other physicians operating in the hospitalist system. Hospital-based specialists typically serve as consultants to admitting physicians. Because hospitalists, due to their increased experience, are more familiar with common inpatient conditions, their need for specialty consultations is less than that of nonhospitalist admitting physicians. This has an effect on the volume of consults and the income of consultants.

Generally, residents have been happy with the quality of teaching provided by hospitalists, ranking them higher than traditional attendings. However, because of their greater expertise in patient work, it can also be expected that hospitalists will threaten the autonomy of residents. They tend to have an increased physical and intellectual presence on the wards.

Discontinuity of care is a consequence of changing physicians when moving from the outpatient to the inpatient setting. The associated concern is a gap in information about the patient’s wishes and clinical state during the transition. The outpatient clinician loses care of the inpatient, and the hospitalist loses follow-up care when the patient is discharged. This discontinuity is often addressed by hospitals by developing programs to enhance communication. These efforts commonly include the prompt calling of outpatient clinicians on admission and discharge and faxing discharge summaries.

Evidence suggests that patients accept hospitalists without significant difficulty. Generally, they are satisfied with the quality of care and do not perceive significant differences between hospitalist care and that provided by their outpatient clinician or traditional ward attendings. It has been suggested that patients may be willing to trade the familiarity of the outpatient clinician for the enhanced availability of their hospitalist. It has also been suggested that patients may no longer be as emotionally bound to their physicians. Many patients have no regular outpatient physician. Furthermore, in the current insurance environment, patients may switch health plans and providers with frequency.

Increasingly, training programs in psychiatry, medicine, and pediatrics emphasize ambulatory care. This raises questions about the adequacy of preparation of recent graduates for inpatient attending. Training programs may need to be revised to provide appropriate preparation for the hospitalist role.

Physicians who wish to provide both inpatient and outpatient care may be unhappy with the hospitalist model. For many ambulatory physicians rotating responsibility allows physicians to maintain inpatient care skills. Some ambulatory physicians are uncomfortable with the potential loss of these skills.

PROFESSIONAL ORGANIZATIONS

The National Association of Inpatient Physicians is a nonprofit organization founded in 1997. It is dedicated to advancing the practice of inpatient medicine and promoting excellence and efficiency in clinical care. It is affiliated with the American College of Physicians. There is no analogous professional organization for psychiatrists.

SPECIALTY TRAINING AS A HOSPITALIST

Increasingly, training programs are geared toward providing only enough inpatient training so that graduates are capable of caring for acutely ill outpatients. Special tracks may be developed to provide adequately trained hospitalists. These programs would focus on developing clinician-teachers with the skills and knowledge necessary for inpatient practice. Sufficient outpatient experience would be provided so the hospitalist would comprehend what level of severity can be managed in the outpatient clinic. In medicine, tracks exist at both the resident and fellow levels.

As the training of hospitalists becomes common, one emerging possibility is the development of two types of residencies. One would emphasize ambulatory care, and the other would focus on hospital-based care. This would evolve through the use of different tracks for residents. In psychiatry, this separation would be expected to occur after the first two years, which usually emphasizes inpatient and consultative work.

FINANCIAL, POLITICAL, AND ORGANIZATIONAL ISSUES

In many hospitals, the reimbursement for inpatient care is such that revenues from hospitalist services are insufficient to provide for the costs of physicians to staff the hospitalist program. In many cases, the benefits to the hospital or, in the academic medical center, to the training program are sufficient to justify additional program support. In academic programs, the training and service obligations are often thought to justify the additional cost.

The willingness of ambulatory care physicians to forgo inpatient care has been heavily influenced by the relatively low compensation. Many have realized that they can increase their clinical income by substituting relatively higher-paying outpatients for lower-paying inpatients and avoiding the unreimbursed commutes to the hospital.

However, it is the low rate of reimbursement for inpatient care that complicates the implementation of the hospitalist model. Low reimbursement along with a payer mix that often includes uninsured patients means that few hospitalist programs can support themselves solely on professional fees. Further complicating the picture is the fact that clinicians are reimbursed a single professional fee each day despite commonly interacting with the patient several times a day and also working with allied professional staff and families. The net result is, commonly, a significant shortfall in the revenue needed to pay hospitalist physicians at a rate commensurate with community norms for other physicians. Generally, hospitals are able to generate about 60% to 80% of their salaries by fee-for-service billings and/or capitation dollars. Because of the benefits they provide to hospitals, practice groups, and other sponsoring agencies, these groups commonly supplement the shortfall in professional fee income.

The hospitalist model will have an effect on a hospital's income. Cases that are paid on a per diem basis may produce less income because of the shorter LOS that occurs with hospitalist attendings. In a capitated case rate in which the hospital is paid according to diagnosis-related groups or when a medical group is paid on a contract rate, there are clear benefits from the reduced lengths of stay and reduced use of ancillary tests associated with hospitalist attendings. In such situations, the savings that result from the use of hospitalists may exceed the salary support provided by the institution. This significant savings is the rationale for supporting the salaries of hospitalists.

To avoid the perception of a conflict of interest, most institutions avoid paying hospitalists to reduce the utilization of services. However, many programs have created incentives related to outcomes measures and patient satisfaction.

HOSPITAL MEDICINE AS A NEW SPECIALTY

Fellowships are currently very limited. Typically they focus on training clinical educators and provide a curriculum on teaching theory, curriculum development, and evaluation methods and opportunities to strengthen teaching skills, along with opportunities to receive feedback about teaching activities. Some also provide instruction on research methods and encourage clinical research activities.

In many institutions, hospitalist positions are staffed by recent graduates and are intended to be transient. In these settings, the opportunities for long-term career development are unclear. In contrast, academic settings that intend to develop a stable cadre of hospitalists provide protected time for promoting scholarly activities and working on improvements in the hospital system.

Traditionally academic medical centers have been challenged in attempting to recognize the contributions of clinician-educators. It is these accomplishments that are the basis of being rewarded with promotion through the professorial ranks. Customary measures of accomplishment include publications and grants, along with other objective evidence of regional, national, and international recognition. The challenge has been to apply these assessment standards to the provision of clinical care or teaching ability. Traditionally, teaching capabilities have been assessed by peer and student evaluations. More challenging is the assessment of clinical excellence.

Hospitalists, similar to emergency medicine physicians and critical care specialists, are site-defined specialists. That is, their area of expertise is not defined by an organ or procedure but by where they deliver care. As such, they care for patients with a variety of illnesses and ages within that location.

In medicine, there are other attributes associated with a subspecialty. There is a large group that identifies themselves as hospitalists. There is a professional society with regular meetings. There is a clinical textbook. Clinicians agree that there is a core skill set and body of knowledge.

FUTURE DIRECTIONS

The hospitalist movement is rapidly growing in psychiatry, medicine, and pediatrics. In the latter two areas, where the numbers are more clearly known, the number of hospitalists is larger than those in many board-certified subspecialties. The hospitalist movement, similar to prior trends in emergency medicine and critical care medicine, has a defining environment and a correspondingly separate body of knowledge and skill set.

Hospitalists can be expected to have an increasing role in improving care for hospitalized patients. Due to their extensive familiarity with the workings of the hospital, they are able to identify system problems and help both hospital workers and staff in dealing with stressful situations, including catastrophes, pandemics, and others. They are able to work with administrators and nurses to ensure that necessary equipment is available and proper protocols are in place to facilitate quality care.

Hospitalists have developed related research areas. Typically these are outcomes-oriented studies that focus on hospital care. Examples include quality of care, cost containment, resource utilization, and LOS. Such studies are typically conducted by academic hospitalists at university medical centers.

The digital health movement is changing healthcare across all disciplines, and hospitalists are likely to contribute to the enhancement of electronic health records (EHRs), particularly to ensure their reliability and portability to outpatient providers. While documentation in EHRs can be time-consuming, ultimately, EHRs improve hospital care by providing clear and reliable documentation, in contrast to the hand-written notes of the pre-digital era. Since these EHRs are often accessible to outpatient clinicians, EHRs also facilitate continuity of care.

Currently, the term hospitalist does not refer to a subspecialty. In medicine, there is a growing effort to make the hospitalist a subspecialty with residency requirements and board certification. The future may see similar trends in psychiatry.

Unresolved questions about the future of the hospitalist movement remain. For example, should hospitalists be exclusively inpatient providers, or should there be some component of outpatient or consultative work? Should all inpatient care be delivered by hospitalists, or is there also a role for outpatient clinicians in the inpatient setting? How will hospitalists be compensated, and who will employ them? What is the optimal training to be a hospitalist?

As the acuteness of inpatients increases, the demands of the job increasingly resemble emergency medicine department attendings or intensive care specialists and are less like outpatient primary care clinicians. Whereas current compensation for inpatient and outpatient physicians is similar, it can be expected that compensation for hospitalists will also increasingly resemble that of intensivist or emergency medicine physicians.

Unique to psychiatry, there is a certain lack of recognition of the hospitalist physician as a differentiated area of practice. In other areas of medicine, the hospitalist role is widely recognized. Despite a long history of the hospitalist role in psychiatry, a role that dates back to the origins of the profession, few psychiatrists who work predominantly in a hospital setting would consider themselves to be hospitalists. They are more likely to call themselves unit directors, ward directors, or attending physicians. As the recognition of psychiatric hospitalists increases, a further appreciation of the similarities and differences between psychiatric hospitalists and hospitalists in other areas of medicine can be expected. One can expect, for example, that the activities of colleagues in other areas of medicine will provide guidance for improving the career path for hospitalists, starting with fellowships and progressing through various levels of seniority following training.

Under-recognized and poorly characterized, psychiatric hospitalists can be expected to be at the forefront of interactions with third-party payers that seek to alter the nature of psychiatric hospitalization. Improved recognition of their role, clarity of their training pathway, and identification of the stages of professional career development will promote this career pathway to trainees and ensure that there are well-trained individuals providing expert inpatient care.

56.6 Psychiatric Rehabilitation

LUJAIN ALHAJJI, M.D., VANESSA PADILLA, M.D., AND RADU V. SAVEANU, M.D.

Mental illness represents one of the leading causes of disability, with depression being a major cause of disability worldwide. Serious mental illness (SMI) results in severe significant impairment in functioning. Psychiatric rehabilitation can have a dramatic impact on improving functioning, independence, recovery, and integration in society. The field of psychiatric rehabilitation continues to grow and evolve. While initially thought of as a series of psychosocial interventions that were aimed at augmenting psychopharmacologic approaches, it has now become collaborative, integrative, multi- and interdisciplinary. Multidisciplinary care ensures that patients' biologic, psychological, and social factors are recognized and interlinked. Patient-centered approaches are imperative in reaching personal recovery outcomes.

For a successful outcome of psychiatric rehabilitation, a patient-centered, holistic, and strength-based approach needs to be implemented. A comprehensive understanding of the patient's psychiatric conditions, treatment regimen, social support, contextual cues in the environment, and individual strengths and limitations needs to be incorporated.

Psychiatric rehabilitation is intended for people living with severe mental illnesses (SMIs) such as schizophrenia, bipolar disorder, or schizoaffective disorder, as well as for those with treatment-resistant major depression, severe anxiety disorders, and substance abuse (alone or as comorbidity). Desired long-term outcomes should involve increased autonomy, subjective sense of well-being, financial independence, and improved quality of life in addition to focusing on remission and symptom control. Many persons with schizophrenia may achieve control over positive symptoms, such as hallucinations and delusions, but still have to deal with negative symptoms that impact communication, initiative, and interpersonal interactions. Neurocognitive symptoms of schizophrenia have been implicated in reduced ability to function in the home, workplace, and community. However, these cognitive effects extend well beyond issues with memory, processing speed, and executive dysfunction. Indeed, some of the greatest difficulties with community functioning are related to deficits in social cognition, including perception and processing of affect, knowledge of social rules and conventions, inferring another person's intentions, as well as attributing causality for positive or negative outcomes. For example, people living with schizophrenia may struggle with inferences or attributional biases. Lack of insight into one's own processes and misinterpreting the emotions and intentions of others can lead to isolation, limited meaningful interpersonal contact, difficulties dealing with others in the community, and problems with interacting with others in the workplace.

Psychiatric rehabilitation strategies are increasingly holistic, integrative, respect the autonomy of the individual in decision-making, and specify incremental, graduated goal attainment with the goal of optimal function in the community. Functional outcomes and improved quality of life remain important aspects of psychiatric rehabilitation. Providing integrative and early psychiatric rehabilitation services that incorporate mental health, substance abuse, and medical health care service delivery can ameliorate the burden of disease, reduce symptomatology, increase employment and productivity, and improve the overall sense of well-being.

PSYCHIATRIC REHABILITATION IN THE MEDICAL SETTING

People living with SMI have an overall poorer health condition than the general population, with a higher prevalence of common conditions including cardiovascular disease, metabolic syndrome, and HIV. They are also at a higher risk of comorbid substance use disorders (SUD), most commonly nicotine use, which may further precipitate, worsen, or exacerbate medical issues. Persons living with schizophrenia are more likely to suffer from obesity, and treatment with antipsychotics further increases this risk. In addition, lifestyle and social factors such as poor access to healthcare services, lack of education or access to nutritious food, financial constraints, and lack of exercise can all contribute to poorer overall health. Inflammation may also play a role in elevating risk factors for chronic medical conditions. Moreover, by facing stigma in their personal lives, persons with SMI may be dismissed by healthcare providers who attribute their somatic complaints as psychiatric in nature. Persons with psychiatric disabilities can face barriers in advocating for themselves and communicating effectively with their health providers. General poor health among individuals with psychiatric disabilities negatively impacts their ability to pursue education, gain employment, become financially independent, and be productive members of their communities.

Psychiatric rehabilitation was previously considered a psychosocial treatment program that focuses on aspects such as social skills training (SST), vocational remediation, and building environmental supports. It is now recognized that many psychiatric disorders need to be conceptualized as chronic conditions with relapses and remissions; hence, psychiatric rehabilitation has also evolved to include psychosocial as well as medical approaches. Persons with SMI may struggle with treatment adherence which can lead to exacerbations of underlying psychiatric, substance use, and medical disorders. As a result, a major focus of many current psychiatric rehabilitation approaches is to facilitate adherence to medical treatments and medication regimens as a primary focus of psychiatric rehabilitation. This is typically achieved by using advanced therapeutic and behavioral techniques. Motivational interviewing is also often used to elicit a patient’s ambivalence relating to taking medications as recommended. With growing technologic innovations, the integration of electronic reminders and innovative smartphone solutions such as mobile apps have also expanded. An emphasis on cognitive and behavioral training with regard to prospective memory, or “remembering to remember,” an intended action is emphasized to promote medication adherence. Further, it is well accepted that medication compliance is likely going to be higher with concomitant efforts to build a supportive environment by preparing the individual to deal with environmental stressors and promoting a physically and emotionally healthy lifestyle. For example, there is a bidirectional relationship between diabetes and depression, with depressed patients having increased challenges to comply with self-management of their diabetes (glucose monitoring, taking medications, following strict dietary recommendations, and exercising, among others). Collaborative care models shared medical appointment models, and cognitive-behavioral therapy (CBT) for adherence and depression (CBT-AD) are available strategies to assist patients with diabetes to improve their medical care management. Integrating approaches to care requires the coordination of several health care disciplines.

UNIFYING CONCEPTS OF PSYCHIATRIC REHABILITATION AND TREATMENT

Successful approaches to psychiatric rehabilitation involve the integration of medical, psychological, and psychosocial approaches. As described below, psychiatric rehabilitation is more person-centered and needs to be tailored to individual needs and goals. Collaboration between rehabilitation team members and patients is vital as this enhances therapeutic alliance, partnership, autonomy, and shared decision-making on behalf of providers, patients, and their families. This partnership in shared decision-making takes into consideration the patients' and their families' specific needs, as well as their cultural beliefs and values. This individualized approach to treatment also emphasizes targeted goals that are unique for an individual patient with the appropriate combination of therapies that are specific to the person's needs.

It is of essential importance for both the patient and the treatment team to (a) identify targeted short-term and long-term goals that are operational and obtainable; (b) plan a sequence of interventions and support systems that are appropriate to an individual's stage of recovery; (c) build in social and environmental supports, stress management, coping strategies, and other continuing therapies that will reduce the chances of relapse; and to (d) continue a collaborative treatment milieu between the patient, family, and care providers that provide the greatest opportunity for mutual respect and decision making. Collaborating with the patient as an active participant in their rehabilitation journey means that treatment becomes educational as well as treatment-focused.

PSYCHIATRIC REHABILITATION AND INCORPORATION OF PERSON-CENTERED RECOVERY MODELS

In the United States, the New Freedom Commission on Mental Health (2003) recognized the voices of the recovery movement and mandated that recovery be consolidated into all facets of mental health policy. The person-centered approach was cited as a vital aspect of recovery, as defined by the U.S. Substance Abuse and Mental Health Services Administration (Department of Health and Human Services, 2004). Collaborative, person-centered approaches to care planning are increasingly recognized as instrumental in accelerating personalized recovery goals. Person-centered care core principles include the development of respectful relationships between providers and people experiencing SMI; the integration of the person in identifying individualized goals; the significance of involving personal, family, and community-based resources to reach those goals; a recognition of responsible risk-taking as a necessary part of growth and recovery; and a focus on acknowledging the strengths and capacities of the person as an essential step to recovery.

This integrative method requires a multidisciplinary or interdisciplinary team approach. The person-centered approach builds upon this by actively engaging the patient and their family in shared decision-making to cocreate an action plan toward recovery such as medication use and incorporates their personally relevant goals and unique psychosocial circumstances into the formulation of treatment plans. Family involvement may especially be important for individuals from diverse cultural backgrounds who value family input. Family-focused recovery may play a key role for some people living with mental illness, as their individual and family needs may be better understood by the family as a group and incorporated into the recovery plan. Encouraging the individual to actively engage in recovery planning can help them develop the confidence and skills needed to regain control over their lives.

The person-centered approach is in line with a more optimistic vision for the long-term recovery of the seriously mentally ill as it offers opportunities to generate higher levels of motivation in patients. These progressive changes in ideology have mostly been championed through the ongoing leadership of federal, state, and local agencies. Many training programs are more cognizant about teaching emerging healthcare practitioners about the person-centered, recovery-oriented mode of service delivery, which is expected to continue to intensify and develop in the coming years given that this approach is expected to strengthen the therapeutic alliance, promote greater motivation and collaboration, and achieve better outcomes. It is vital to follow the same person-centered approaches with all patients, with a focus on valued outcomes, while also tracking and measuring outcomes of success of services provided over time.

DEFINING RECOVERY

Outcomes of psychiatric rehabilitation can vary given the heterogeneity of SMI and the wide variety of services available. Reaching recovery goals can hence vary based on the patient’s own targets, as well as personal attributes, social environment, continuity and quality of treatment, and subjective experience.

Sustained recovery is a long-term process and refers to long-term abstinence or remission of symptoms and return to normal psychosocial functioning. Recovery allows persons living with SMI to improve their overall health and wellness, lead self-fulfilled lives, and empower themselves to reach their full potential as contributing members of their community. It can be measured by a set of processes, stages, and outcomes that are based on mediating and moderating variables that facilitate its attainment and maintenance. That is, recovery is an outcome of the process of recovering.

Hope, destigmatization, empowerment, self-acceptance, insight, awareness, collaboration with professionals, sense of autonomy and self-control, as well as participation in self-help and patient-run programs, are all attributes that may help individuals progress toward recovery. Subjective experiences and attributes mediate the process leading to recovery and also sustain recovery. For example, a treatment or self-help program may engender a feeling of empowerment, which can be instrumental in motivating a person to sustain treatment and rehabilitation until recovery can be achieved. Once recovery has been achieved, empowerment may be even more firmly experienced through continuously improved functioning and cognitive, social, and emotional stability.

Many factors can influence recovery, including overcoming and managing one’s symptoms, choosing healthy outlets and appropriate treatment to support one’s general well-being, having access to healthcare and stable housing, obtaining purpose and meaning from one’s life, including having enjoyable daily activities, financial independence, and contribution to one’s community, and having supportive relationships. Rehabilitation services must remain flexible in the services provided to individuals and continue to advocate for their patients, reduce health disparities, improve access to care, and ensure that care delivery supports their patient’s sustained recovery.

Similarly, having hope for future improvements in quality of life may be reinforced by the enthusiasm and collaborative alliance embedded in a therapeutic relationship. Many patients who have written first-person accounts of their recovery have pointed to the importance of a long-term relationship with a practitioner who refused to give up hope for the patient’s ultimate improvement and recovery. Hope can serve to fuel motivation for change and for active participation in clinical services or self-help, which are stepping stones toward recovery. Subjective experiences of empowerment and hope continue to grow after a state of recovery is attained, contributing to further strengthening and protecting individuals from stress-induced relapse. Encouragement and hope also enhance efficacy expectations that empower the individual to assume greater control and responsibility for their lives.

EMPIRICALLY BASED MODELS OF PSYCHIATRIC REHABILITATION

Psychiatric rehabilitation has evolved from being considered an add-on treatment if conventional measures with psychotropic medications or psychotherapy fail, to a way to “fill the day” with activities for persons with SMI, with descriptions of the token economy of other reinforcement programs. Psychiatric rehabilitation has moved to become an evidence-based, highly specialized specialty within psychiatry, offering structured interventions, assessment tools, and defined target goals in order to reach desired individualized outcomes in persons with SMI. Evidence-based practice recommendations are based on well-designed research studies that show effective interventions in improving illness course and outcome.

Over 50 years of intervention research has led to the expectation that even patients with the most severe mental disabilities can improve their overall daily functioning when provided with empirically validated, evidence-based behavioral interventions. Some examples of evidence-based practices (EBPs) for the recovery of SMI include assertive community treatment (ACT), cognitive-behavioral therapy for psychosis (CBTp), cognitive rehabilitation, family psychoeducation, illness self-management training, SST, and supported employment, among others. Some other forms of interventions are gaining more evidence, though not yet evidence-based, such as expressive and art therapy in patients with schizophrenia.

In 1991, the Americans with Disabilities Act was signed into law, requiring equal employment opportunities and reasonable employer accommodations for workers with mental illness. Moreover, fulfillment of interventions for therapeutic improvement has been facilitated by political advocacy, destigmatization of mental illness, and self-help activities of consumer organizations such as the National Alliance for the Mentally Ill, the Schizophrenia Fellowship, and networks of mental health clients.

Recovery is now more than ever a realistic goal for many persons with mental disabilities with enduring biologic vulnerabilities such as schizophrenia; however, it is necessary that the full range of evidence-based biopsychosocial services be available in a continuous, accessible, comprehensive, coordinated, person-centered, culturally appropriate, and competently delivered system of care. Despite the fact that the field of psychiatry produces a wide array of evidence-based treatments and services, public and private funding has eroded for organizing and delivering these services with high fidelity. With that in mind, psychiatric rehabilitation is confronted with the major challenge of fiscal limitations, inadequate resources, and poor coordination. Two core principles of psychosocial rehabilitation include: (i) all resources allocated to the recovery process should be coordinated and integrated with the goal of optimizing treatment, and (ii) a consistent therapeutic team should provide continuity of care, taking into account the person's life context.

ACCESSIBILITY TO EVIDENCE-BASED TREATMENT AND SERVICES

Despite the growing evidence available on psychiatric rehabilitation, there is a wide gap between the scientific literature and the design and practice of many psychiatric rehabilitation programs. This means that evidence-based psychiatry rehabilitation interventions are not widely available, nor easily accessible, in day-to-day clinical practice. Funding opportunities may be limited and can hinder the development of these programs. In addition, there are many differing opinions among psychiatry professionals in relation to views on recovery and treatment goals, as well as patient and family expectations, which can further prevent the restructuring of existing programs and the new development of quality-based programs.

One of the biggest hurdles in implementing evidence-based rehabilitation programs and improving access is organizational level challenges, competition in allocating funds to resources, a lack of administrative and financial integration of state and local community mental health and substance abuse services, and, at times, a limited understanding of mental health needs beyond symptom control. While the

United States revolutionized the concept of evidence-based rehabilitation services, it appears that the existing services fall behind other high-income countries. The consequences of those system-wide problems have meant that too few individuals with mental disabilities are receiving state-of-the-art services and too many thousands end up living on the city streets or in jails and prisons.

Implementing recovery-oriented and person-centered programs can take a long time, requiring the commitment of providers to not only practice but also train and educate others entering the field. Conducting continuous measures and tracking outcomes is vital for quality measures. Engaging learning environments, such as training events and user-friendly practical guidelines that support clinical decision-making, can be helpful in training future rehabilitation providers. An example of this includes the development of a free evidence-based resource center from the Substance Abuse and Mental Health Services Administration (SAMHSA), which provides toolkits available on their website: https://www.samhsa.gov/resource-search/ebp. These efforts, such as the project implementing EBPs, have mostly been sponsored by federal, state, and foundation agencies. Standardized guidelines for the application of the evidence-based treatments are provided in workbooks that are included in the toolkits focused on improving the functioning, quality of life, and recovery of patients, as are training materials and procedures to provide means for assuring high-quality treatments.

The American Psychiatric Association (APA) has also provided free-access training materials for psychiatrists on basic understanding of recovery from SMI and SUDs and recovery-oriented care. These training videos can be accessed at https://www.psychiatry.org/psychiatrists/practice/professional-interests/recovery-oriented-care.

The ultimate purpose of any available EBP toolkit—“to promote the implementation of evidence-based psychosocial treatments in routine mental health settings’’—is a goal that has great potential to improve the lives of people diagnosed with serious mental health disorders. Access to EBP Toolkit helps clinicians, agencies, and organizations to be educated in facilitating best practices in the training, implementation, and monitoring of evidence-based treatments for mental health. However, implementing and directly monitoring fidelity to the model can be a costly and time-consuming process. A balance needs to be achieved between monitoring the accurate implementation of each EBP while promoting its dissemination in a way that allows institutions to tailor the innovation to fit the specific function, mission, patient population, local resources, and other contingencies they face. Continuous quality improvement has been used effectively as an approach to implement EBPs in community-based settings.

At the level of the community agency implementing EBPs, specific expectations for clinician performance and ongoing program evaluation, as well as a culture change, are required to implement and sustain the provision of EBPs. Thus, evaluating the cost-effectiveness of the EBP toolkits using a longitudinal time frame and a methodology that captures the organizational characteristics and the total expenditures to the systems of care in using the EBPs for the patients within their catchment areas is essential to the long-term viability of these programs.

With improved and more reliable diagnostic methods, as well as symptom and functional assessment and an empirically validated definition of recovery, the population and needs of patients requiring psychiatric rehabilitation are becoming better defined. Methods for determining readiness for rehabilitation also have been validated, enabling administrators and providers to be more efficient in allocating rehabilitation programs and resources. Because of its growing technology and its conceptual and empirical base, psychiatric rehabilitation has attracted an interdisciplinary group of practitioners and investigators whose work has contributed to its evolving scope and stature.

The challenges to community-based care for persons with serious and chronic mental illness have been met partially by new initiatives at the clinical and policy-making levels. New interventions have been designed and validated, such as psychoeducational and behavioral family therapies, SST, CBT for medication-resistant psychotic symptoms, intensive case management models for assuring continuing care, supported housing, and employment services. At the level of psychiatric politics, consumers and families have become empowered by the advent of peer-directed self-help organizations; the use of social media for the education of the public about mental health disorders and the possibilities for recovery, including noted political, sports, and entertainment figures going public with their experience of living with mental health disorders and successful treatment; legislative lobbying, assertive advocacy, peer support, and family involvement in treatment; efforts to gain parity in funding for mental health services; and the Americans with Disabilities Act regulations.

The COVID-19 pandemic has brought on many challenges in mental health care delivery. Provision of rehabilitative care for persons living with SMI is vital to monitor COVID-19–related recovery outcomes, including the accessibility of services, healthcare disparities, rate of relapses and symptoms exacerbations, rates of telehealth encounters, patient and family satisfaction with the quality of care, functional, social and vocational outcomes.

REHABILITATION IN THE PRODROMAL, ACUTE, AND STABLE PHASES OF SEVERE MENTAL ILLNESS

Effective treatment and rehabilitation of persons with SMI require clinical services that are linked to the phase of their disorder. For most stress-related, recurring, and disabling mental disorders, the following phases are relevant for practitioners' initiating and/or adjusting their treatment:

- Motivation and engagement in treatment
- Prodromal
- Acute
- Stabilizing
- Stable
- Recovery
- Refractory

There is broad-based variability in the manner in which individuals experience a particular phase in that no two individuals experience any phase in the same way. Individual differences influence each phase in terms of severity, duration, degree of disability, resolution, course, and boundaries. The following cases depict two persons in the stabilizing phase. This serves to exemplify the need to adapt treatments to individual diversity within a particular phase of illness.

Mr. B, a 19-year-old male, was admitted for involuntary psychiatric hospitalization after he locked himself in his room for three days and refused to eat because he was afraid someone was poisoning him. His father would hear him talking and yelling to himself incoherently. When his father was able to enter his room, he found the room to be in disarray with the windows covered with newspapers, as Mr. B thought he was being watched. After six days of stabilization, he was released from the hospital and returned home to his father but was still very anxious about being alone, had difficulties with hearing voices telling him he was “cursed,” and was extremely concerned that his movements were being monitored. Because he was resistant to oral medications (he thought they might be meddled with and might poison him), he was prescribed a long-acting injectable antipsychotic, which helped to stabilize his symptoms. Upon returning to school, he completed a semester taking a reduced course load and living at home. However, during the next semester, he insisted on taking a full course load and started to smoke cannabis and other drugs to help manage the resultant distress. He began to feel on edge and felt that others in his class were judging him critically and talking about him. His grades started to deteriorate, and Mr. B developed another acute psychotic episode. He was readmitted to the psychiatric hospital with extreme paranoia and had to again drop out of school. This time, treatment became integrative, and, in addition to adjusting his psychiatric medications, he received supportive psychotherapy and was engaged in several cognitive-behavioral and skills-building training that provided him with ongoing support and structure. He learned to be more assertive and comfortable in his interactions through assertiveness, social skills training, and relaxation/stress management techniques, which greatly helped his coping skills. Mr. B eventually returned to school, earned his degree, and is currently in a supportive work program.

Ms. A, age 24 years, had persistent depressive symptoms that increasingly became worse, particularly when she graduated from medical school and accepted a role as an internal medicine resident in a busy county hospital. She became increasingly convinced that she was an unqualified physician despite graduating with honors and felt hopeless and worthless. She consistently felt that she was subpar compared to her peers, which further perpetuated her sadness, hopelessness, and her sense of failure. As a physician intern, she struggled to complete necessary clinical duties due to fatigue and impaired attention and concentration. On top of existing insomnia with difficulty falling and staying asleep, transitioning to night shifts further impaired her sleep. Her husband noticed that she was becoming more isolative, tearful, and was not interested in joining her residency group activities or completing house chores. Her family started to become increasingly concerned about her lack of communication and began to worry about her engaging in self-harm behaviors. Ms. A. started to feel that she was a burden to others and began to think about death. On an evening shift, she encountered a verbally hostile patient who demanded to transfer his care to a different provider. She then became acutely suicidal and was subsequently admitted to an inpatient psychiatry unit for treatment and stabilization of her severe depression. Following discharge from the hospital four days later, she was placed on a combination of antidepressant and antipsychotic medications and immediately referred to a psychotherapist who focused on CBT techniques. It took several weeks before she was adequately stabilized to engage in interventions for major depression and suicide prevention. In addition, Ms. A and her husband started couples' therapy with another therapist that helped the husband better understand her illness, supported her behavioral homework, and helped the couple to communicate better. Ms. A, with the help of her supportive residency program director, is now back to work, with an adjusted on-call schedule, and is involved in maintenance therapy where she sees her psychotherapist weekly and continues to adhere to all her mental health treatment.

STABLE PHASE

FIGURE 56.6–1. Multidimensional framework for phase-linked treatment and rehabilitation.

These two examples illustrate the need to conceptualize the treatment of these two individuals into several components (a) stabilization; (b) dealing with ongoing acutely psychotic, mood, or anxiety symptoms; (c) using the therapeutic alliance to provide the maximum motivation for treatment; (d) using integrative therapeutic support to augment and strengthen the possibility of positive treatment results; (e) ongoing assessment and strategies aimed toward relapse prevention; and (f) reinforcement and maintenance of gains.

The framework for phase-linked treatment and rehabilitation is depicted in Figure 56.6–1. It should be noted that EBPs are the backbone of services generally found to be useful for patients as they traverse the various phases of their disorder. There is considerable variability in how fast each individual moves from one phase to another, and progression may not be linear in fact. Some may even skip a phase, becoming stable within one week of an acute relapse, without the gradual stabilization of symptoms and functioning that is more frequently the case. People also move back and forth between phases as stressors impinge on their vulnerability, and the individual has not compiled sufficient protective factors.

Prodromal Phase of SMI

Early identification, engagement, and treatment are the mainstays of this phase, which may be associated with individuals who are at risk of their first episode of SMI or are experiencing the warning signs of a recurrence of their disorder. Preventive interventions for young people at high risk of developing a psychotic illness remain in the early stages of development and need further investigation. Psychosocial and pharmacologic interventions have not been empirically documented as fully effective in averting schizophrenia or other psychotic disorders when provided to young people experiencing prodromal signs and symptoms. The sensitivity and specificity of identifying the early signs of a developing psychosis have not been fully validated; however, recent review studies suggest that “basic symptoms” (defined as ‘subtle, subclinical disturbances in one’s experience of oneself and the world that prospectively predict first episodes of psychosis’) can improve the prediction of psychotic relapse. Further prospective studies are still needed to compare basic symptoms and early signs as predictors of psychotic relapse. Moreover, in the digital era, some studies have focused on social media activity (primarily via patterns of linguistic and behavioral changes) and the use of machine-learning models to identify and predict psychotic relapse in young individuals with recent-onset psychosis and imminent risk of hospitalization.

Youth who are possibly moving toward their first psychotic episode may experience sleep problems, strange, unusual, unwanted, and intrusive thoughts, depression, irritability, hypomania, or anxiety. Other prodromal signs and symptoms include ideas of reference, paranoid worries and fears, significant social and emotional withdrawal, suspiciousness, apathy and loss of drive, disturbances of attention and concentration, functional deterioration, odd behavior, perceptual abnormalities, and derealization. These young people almost always refuse to accept professional intervention, preferring to think that their condition is transient and will dissipate without psychiatric treatment. Moreover, the stigma of mental illness is a major deterrent to obtaining treatment.

For these individuals and their families, a patient-centered, nonconfrontational stance is desirable. Because it is not even certain that they are moving to an acute psychotic episode, it is necessary to monitor the presenting symptoms and how they might be interfering with the individual's current life. Then, depending on the specific problems that are interfering with the individual's reaching their goals, the psychiatrist points out that treatment may very well help to overcome the obstacles to progress toward these goals. This approach is known as motivational interviewing and represents a strategy for engaging patients in early treatment. It may be necessary for the practitioner to ally with the family so that the latter can join in the motivational enterprise. The treatment approaches to this early developmental phase of schizophrenia are delineated in Table 56.6–1.

Symptoms Prodromal to a Relapse. Because each psychotic episode places the individual at greater risk of prolonged psychosis, disability, and refractoriness to treatment, prevention of relapse has been assigned a high priority. It is often the case that the individual with recurrent illness does not recognize or acknowledge their symptoms; in this case, it is best to simply work on building a relationship with the patient that will eventually pay dividends for active treatment once trust has been achieved or restored.

Table 56.6–1.
Interventions for the Prodromal Phase of Schizophrenia in Young Persons Not Yet Diagnosed with the Disorder

1. A psychoeducational approach is directed to the patient, family, other caregivers, primary care physicians, school counselors, and staff at college counseling centers. The psychoeducation must be keyed to the particular needs, readiness, and role of the individuals who are in a supportive relationship with the individual who is experiencing the prodromata to a serious mental illness. Outreach and liaison with “gatekeepers” to mental health services—primary care physicians, clergy, schoolteachers, and school counselors—is important for mental health facilities and solo practitioners to mount a successful effort in identifying young individuals at high risk of a serious mental disorder. There should be ongoing liaison, education, and consultation with the family and referring professionals and agencies.
2. Nonstigmatizing, age-appropriate, culturally congruent services should be offered in a youth-friendly, nonclinical environment.
3. Specific treatment for symptoms and behavioral problems that are interfering with the young person’s goals and functioning should be adopted:
    a. Motivational interviewing.
    b. Stress management.
    c. Cognitive-behavioral therapy or interpersonal therapy for anxiety and depression.
    d. Cognitive-behavioral therapy for prepsychotic symptoms.
    e. Supportive relationship that permits open discussion of the young person’s concerns, worries, symptoms, and progress toward goals.
    f. Antipsychotic medication at low dose for symptoms that do not respond to psychosocial interventions and continue to impede the young person’s functioning.
4. There should be frequent re-evaluation of the patient’s clinical status to determine whether a schizophrenia prodrome is actually operating.

If possible, prior to a recurrence of psychosis, the practitioner should provide illness management services that include training in recognizing and monitoring early warning signs of relapse together with developing an emergency plan for preventing full-blown relapse. This educational effort is important because recurrent episodes of schizophrenia, major depression, bipolar disorder, and other SMIs carry a poorer prognosis and a higher risk of:

- More frequent acute illness episodes in the future
- Higher likelihood of nonadherence to treatment
- Greater difficulty treating each recurrent episode
- More serious disruption of social, occupational, educational, and family roles
- Greater likelihood of stigma and family isolation
- More frequent involvement of police, involuntary admission to hospital, homelessness, and legal problems or incarceration.
- Increased financial and emotional burden for the family.

Early Intervention and Relapse Prevention. One component of illness management is educating patients and their families to recognize the prodromal signs and symptoms of relapse, monitor them, bring them to the attention of the mental health provider, and follow through with their emergency plan to avert relapse. Early intervention during the initial onset of a psychiatric disorder should be implemented to minimize the risk of developing chronic disability.

An acute episode of mental illness, including relapse for persons who have had previous episodes, frequently follows prodromal signs and symptoms for patients with mood and psychotic disorders. Regardless of where a patient resides during an acute episode of illness—crisis home, family home, inpatient unit, or partial hospitalization—the major task is to mitigate overstimulation and provide a safe, secure, supervised, and predictable environment. This is accomplished by offering clear expectations for daily activities, a posted schedule of daily events, discharge criteria, standards for each privilege level, and a structured routine and treatment environment. Staff experienced in working with acutely ill patients offer individualized, clear expectations for behavior and low task demands that are not unnecessarily burdensome but are flexible in terms of how much social interaction is prescribed. In addition, the staff should offer low-key planned and scheduled activities, orientation, and guidance on the rules of the facility by posting visual aids on the bulletin board and whiteboards. One staff member should be designated to help each patient conduct problem-solving and offer supportive therapy at all hours.

In this intervention phase, pharmacologic and behavioral treatments of acutely ill patients are intended to stabilize or eliminate symptoms and improve cognitive status so that the patient can move toward focusing on the development of skills and utilizing the social and professional supports that will help the individual move into the next phase of treatment. Close and prompt postdischarge monitoring is vital. Discharge planning should include not only the assessment of psychiatric symptoms but also consist of access to safe housing, outpatient medical and mental health care, employment, community resources, and social support.

Most patients in the acute phase can begin learning illness management skills, including understanding their symptoms, describing their mental illness and treatment plan, and creating strategies for minimizing its impact on their daily functioning and reducing rehospitalizations. During the acute treatment phase, it is essential to customize skills training and support to symptomatic and cognitively impaired individuals; thus, in educating, it is very important to use strategies such as motivational enhancement, repetition, responsive reading, modeling, role-playing, and problem-solving. It is also necessary to be flexible in using relevant and culturally appropriate communication in educating patients about the value of psychotropic medication use.

Continuity of Care From Hospital to Community. Continuity of care with mental health and other medical providers is essential for improving provider–patient relationships and reducing fragmentation of care. It is associated with greater patient satisfaction, higher adherence to treatment, and reduced hospital service utilization. Due to hospital stays becoming shorter than in the past, patients may be discharged with ongoing active symptoms and may not be sufficiently optimized. Despite efforts by hospital providers to ensure continuity of care and create a postdischarge plan, numerous studies have confirmed the frequent lack of follow-up when transitioning from inpatient to outpatient care.

Patients struggling with persistent acute, distressing symptoms postdischarge from inpatient care may face obstacles when attempting to engage in outpatient services. Cognitive deficits are common in SMI and interfere with the patient taking the initiative or planning to set up a follow-up appointment. Psychoeducation with frank and honest discussions should be conducted with the family involved, as at times, the patient’s support system may believe that definitive treatment has been completed in the hospital, fail to encourage follow-up services, or even suggest discontinuing medications due to lack of psychoeducation or understanding of recovery, as well as the presence of stigma toward mental health care services.

Case managers can help facilitate this transition by coordinating a community mental health liaison to visit the patient while hospitalized to introduce themselves, discuss services, and answer any questions. An outpatient case manager or representative can also accompany the patient to visit their community mental health center for follow-up. This familiarization can reduce anxiety, as the patient will no longer need to repeat their histories which may often be related to traumatic experiences during past acute episodes, and increase the likelihood of follow-up. Providing transportation from the patient's home directly to the facility for their appointments increases attendance and participation.

Training programs, such as the Community Re-Entry Module, empower patients transitioning out of the inpatient psychiatry setting to learn skills and attitudes that support continuity of care. Some of the skills taught include: connecting with the community, planning a daily schedule, making and keeping appointments, and managing medications. These skills allow the patient to take responsibility for making the connection with outpatient services with the purpose of enhancing their quality of life by functioning more autonomously.

In this continuity of care program, family members are involved in the training as much as their schedules permit. A randomized, controlled study comparing the continuity in reaching outpatient services for inpatients who participated in the Community Re-Entry Module versus those who received standard discharge planning by a social worker showed that more than 80% of the individuals participating in the module succeeded in getting to an outpatient facility after leaving the hospital, compared to only 37% of those receiving a standard discharge. This study confirms the capabilities of patients with schizophrenia to take responsibility for maintaining their treatment.

During the acute phase of treatment, some common patient responsibilities include such functional and symptomatic outcomes as engaging in independent self-care and personal hygiene without prompting, socializing with peers without hostility or social withdrawal, voluntarily accepting medication, and learning the reasons why medications are being prescribed—both for dampening the current symptoms that led to the hospitalization and for prophylactic purposes to reduce risk of relapse. The patient and physician review the daily behavioral progress, which is the cornerstone of motivation, hope, and shared decision-making. Most inpatient units have “level systems” that are used to provide incentives to patients to take more responsibility for their self-care, reliability, participation, and behavior. Level systems can be customized to meet the individual needs of specific patients by using tokens, credits, or points superimposed on the level system. Another way to motivate patients to reach their goals and discharge readiness during the acute phase of illness is to use therapeutic contracts. Therapeutic contracts invite collaboration in that both parties describe their goals and responsibilities for the inpatient period of treatment.

The psychiatrist and other staff must ensure that the patient is familiar with and has a plan for reaching follow-up care as an outpatient. As discharge approaches, the responsible psychiatrist should reach out to the family and invite them to attend a psychoeducation meeting with the psychiatrist present to answer questions and give feedback on how their relative is progressing. Having the family present with the psychiatrist and treatment team during a psychoeducational meeting in the acute phase of illness provides opportunities to acquire another source of information about the patient’s illness and disability. Family members may be more reliable assessors, and many of them keep written records or diaries of the course of illness, medications, and responsiveness and side effects of the illness. Home visits seldom occur in the current era; however, this can provide considerable information about the quality of life of the patient in their current environment prior to hospitalization, thereby enabling more accuracy and clinical acumen to be brought to bear on the diagnosis, treatment experiences, and social functioning of the patient.

Stabilization Phase

Stabilization of symptoms and monitoring of cognitive deficits almost always continue after acute discharge into the stabilization phase. Most of the considerations noted previously in the acute phase are continued in the outpatient setting; hence, the treating psychiatrist has the responsibility for ensuring that continuity of care is updated.

Once the patient is discharged from the inpatient setting, it is likely that medications are to be continued. Monitoring symptoms using quantitative scales such as the Brief Psychiatric Rating Scale (BPRS), the Positive and Negative Syndrome Scale (PANSS), or the Target Symptom Scales during regular appointments can help the prescribing practitioner make informed decisions regarding dosing or type of medication changes. Responsiveness to medication is also affected by the emotional climate in the family, which needs to be considered by the prescribing psychiatrist. The use of a quantitative rating scale for the informed use of medications is illustrated by the stabilization of the patient in the following case, a young woman with schizophrenia.

Ms. C, a 30-year-old woman, had three previous hospitalizations with relapse of acute psychosis, exhibiting paranoid delusions and auditory hallucinations. These symptoms were stabilized with antipsychotic medication. The positive symptoms of schizophrenia were much improved after her last hospitalization; however, she reported having “no interest or motivation” and no desire to interact with others. During the first month of outpatient visits, her psychiatrist gradually titrated up her medication, with evidence of stability in that her delusions and hallucinations remitted. However, serial monitoring with the PANSS indicated worsening in her negative symptoms of schizophrenia. A family meeting revealed that the family did not comprehend the effect that negative symptoms could have on Ms. C’s daily functioning despite the lack of active psychosis. As a result, they criticized Ms. C for not returning to work, leading to frequent heated arguments. The psychiatrist scheduled a series of weekly and then biweekly educational sessions for Ms. C and her parents to explore the family structure, expectations of treatment and provide psychoeducation about Ms. C’s illness and treatment. This intervention gradually lowered the “emotional temperature” of the family household, resulting in Ms. C receiving the assistance that she needed in order to engage in vocational rehabilitation.

During the stabilization phase, learning illness management skills, including gaining a more solid understanding of the role of medication, can be very useful. This includes skills such as how to communicate assertively with the psychiatrist about side effects or lack of symptom reduction, as well as how to communicate with friends and family about their illness. Supportive treatment sessions are provided on a weekly or biweekly basis with extended invitations to the family or other caregivers to participate in the training sessions for illness management focusing on proper medication use and relapse prevention.

Illness self-management education involves teaching individuals with SMI about the nature and course of their medical and psychiatric conditions, engaging them in motivational interviewing to explore implementing lifestyle choices that can promote better illness management, instructing them how to monitor their symptoms, how to self-administer medications, and preparing them on signs and symptoms that warrant contacting their treatment providers or seek emergency treatment. Behavioral skills training is useful to address nonadherence to help incorporate taking treatment as prescribed into the individual's day-to-day routine. Developing a relapse prevention plan can be useful to provide a physical, concrete reminder for the patient to monitor their symptoms. Helping the patients develop coping strategies for persistent symptoms can reduce emotional distress.

Collaborative Relationship With Patient. The development of a collaborative and therapeutic relationship is essential if the patient is to remain in long-term treatment and make progress toward their personal goals. Personal, relevant goals are motivating for the patient's participation in the phases of stabilization, stable, and recovery. Depending on the needs and desires of the patient, these goals can be connected to areas of functioning such as self-management, friendship, and intimacy, work or school, family relations, housing, recreation, financial, and spiritual needs. The psychiatrist and other mental health professionals working with the patient must help the patient set incremental, stepwise goals that will bring the patient closer to their overall personal goals.

As symptoms and cognitive impairments stabilize, the patient may benefit from weekly SST that gives the patient opportunities to learn from social modeling, role-play practice, and homework assignments to facilitate achieving short-term goals that are on the pathway to overall goals. For example, a man in his 30s who has reached the recovery phase of schizophrenia may have a personally relevant goal to find an apartment and live independently. With the guidance of the skills trainer, he may proceed through a series of steps, including the following:

- Learning and demonstrating the ability to engage in medication self-management and other Independent Living Scales (ILS) required for living in an unsupervised residence.
- Through problem-solving training, identifying various ways to locate apartments that are for rent, and generating options.
- Evaluating the pros and cons of each identified apartment—for example, costs, location, and availability of public transportation.
- Practicing in the group how to ask questions assertively about the apartment with the property manager or owner, then applying the skills practiced to real-life situations.
- Reviewing the advantages, disadvantages, and feasibility of each apartment and making a provisional choice with second and third preferences.
- Role-playing in the group session on how to request a loan from parents to help subsidize the rent, then carrying out the request with parents.
- Role-playing in the group session finalizing and signing a lease agreement with the property manager, then doing it in real life.

Once he settles into an apartment, there are many more related goals, including furnishing the apartment, meeting neighbors, and identifying and engaging in social events available in the community. Once the individual is successfully established in the apartment, he may again set new personal goals such as making friends and finding a part-time job.

Increasing motivation through repeated successful reinforcing experiences can encourage the patient to establish broader functional goals and reinforce therapeutic alliance with the rehabilitation team. As therapeutic relationships strengthen, so does the willingness of patients to confide in their treatment team.

Involving Families in Stabilization. Families play a major role in facilitating or impeding improvement in patients with SMI—including schizophrenia, mood disorders, disabling anxiety, or somatoform disorders. In many instances, family members become caregivers for persons living with psychiatric disabilities. Involving family members can help prevent relapse, encourage treatment adherence, facilitate a supportive home environment, reduce distress, and promote a fitting level of patient independence. Through rehabilitation efforts, families can be included in planning, monitoring, and promoting stabilization. In fact, mobilizing families as partners in the treatment enterprise is relevant for all phases, including stable and recovery periods.

Relatives and other caregivers can be involved in treatment sessions that are organized either for individual families or multiple family groups, with goals limited to psychoeducation about the nature, course, and treatment of the psychiatric condition or, more extensively, teaching skills in communication and problem-solving, coping with persistent symptoms, managing crises, and implementing relapse prevention plans.

In the stabilization phase, patients should be involved in family sessions as their symptoms and cognitive impairments permit. It is essential that family services be fully integrated with other treatment modalities being offered to the patient, such as social and vocational rehabilitation and medication management. Multidisciplinary integration is accomplished most effectively through regular consultations and interactions among all those responsible for the patient's services. Communication among mental health providers can be initiated and led by the psychiatrist through phone calls, case conferences, team meetings, and virtual platforms. Families can also benefit from participation in educational programs offered by their local National Alliance on Mental Illness (NAMI) affiliates that include Family-to-Family seminars and Homefront meetings for families of veterans, as well as family support groups, educational lectures, and annual statewide and national conferences. For the specific individuals living with SMI, NAMI also offers a free Peer-to-Peer educational program to better understand their illness and their recovery process.

Contact with families should continue indefinitely because they often serve as the most important continuous thread of support that weaves together the various phases of illness. It is now well established that patients living with relatives who learn coping skills from behavioral family management have two to three times fewer relapses than patients who are treated with medication and case management alone.

Stable Phase

Patients are considered stable when their symptoms no longer interfere with their functioning in everyday activities. This does not mean that their symptoms are in remission, although they are usually rated as "moderate," "mild," or "very mild" on the BPRS. Some patients living with schizophrenia, for example, are able to participate in work, school, social, and recreational activities in normative settings even when delusions and hallucinations are present on a daily basis. Psychological interventions can displace symptoms, such as when patients are actively engaged in conversations or tasks that shift their attentional capacity from isolated self-preoccupation. Cognitive functioning, such as attention and planning, can also be improved by cognitive remediation (CR) in this phase of treatment.

Incremental steps toward achieving long-term, person-centered goals continue in the stable phase. Progress toward goals can be promoted by participation in training programs that use behavioral learning principles to assure generalization of skills learned in skills-training sessions that take place in clinical settings. The key to generalization is for clinicians, family members, or peers to promote opportunities and encourage, as well as reinforce the use of skills in the natural environment.

Vocational Rehabilitation. Vocational rehabilitation programs exist to bridge the divide between persons with SMI who are interested in working to gain employment. During the stable and recovery phases, patients may be able to begin job-seeking or return to school. Although supported employment (or supported education) is the most popular evidence-based service for vocational rehabilitation, it is not the only occupational goal that is clinically relevant. A wide variety of vocational and educational activities can be compatible with the stable and recovery periods of functioning. Before some patients are ready for work in competitive jobs, they inevitably need to transition through work-related activities short of regular jobs in the community. The Clubhouse Model of Psychosocial Rehabilitation is an example of a model in place for persons living with severe mental illness who engage in a nonclinical, integrated therapeutic working community to achieve recovery by strengthening work-mediated relationships. Studies have found evidence of the efficacy of the Clubhouse Model in promoting employment, reducing hospitalization, and improving quality of life for those with SMI.

At the same time, it is important to recognize the value of supported employment because patients with mental illness who gain jobs in the competitive sector can work half-time or more in competitive lines of work and can gain satisfaction with their renewed or achieved status as workers. Based on direct comparison analysis and network meta-analysis, supported employment and augmented supported employment have been found to be the most effective interventions for obtaining and maintaining employment for those living with SMI. Supported employment provides persons with SMI an opportunity to obtain competitive employment through a rapid job search and retention, whereas traditional vocational rehabilitation programs provide a “training-place” prevocational training and experience in noncompetitive, structured staff-supported settings with other SMI individuals prior to work placement. Individual placement and support model of supported employment (SE-IPS) also includes collaboration with psychiatric services, counseling on benefits, and counseling on job challenges such as disclosure of psychiatric illness, transportation challenges, and meeting job expectations.

However, not all individuals with mental disabilities wish to participate in supported employment. Many persons living with SMI show ambivalence toward obtaining competitive jobs. Approximately half of those with disabling forms of schizophrenia, mood disorders, and personality disorders do not engage in supported employment. Moreover, supported employment is not always associated with increased self-esteem, quality of life, global functioning, or reduced psychiatric symptoms. There are alternative ways to lead a working life, including an array of opportunities that can be viewed as prevocational in nature, such as volunteer opportunities and on-the-job training.

Various work circumstances can lay the groundwork for recovery. A 2018 meta-analysis reviewed 21 SE-IPS programs randomized controlled trials around the world and found that participants in SE-IPS programs were more likely to obtain a competitive job compared with alternative vocational rehabilitation services (mean risk ratio = 2.31 [95% CI 1.99–2.69]). Competitive employment is associated with improvements in quality of life and with increased self-esteem, reduced stress, increased socialization, and reduced stigma. When seeing themselves as self-directed agents contributing purposefully to their own patient-centered work goals, patients can make progress toward independence and self-sufficiency in a variety of ways as they are able to see themselves working toward recovery.

Recovery Phase

Recovery does not mean “cure”; rather, patients in this phase are empowered to live meaningful and satisfying lives, having reached many of the overall goals that bring them into normal community settings and interactions. In this phase, individuals are more autonomous and self-directed in their choice of person-centered goals and taking steps and garnering resources to continue achieving their goals. They are equal partners with their professional providers of services, making shared decisions and serving increasingly as their own case managers. They often assume paying jobs as peer counselors and peer advocates, in addition to joining with mental health professionals as active proponents of public education and political action for decreasing stigma and improving funding for mental health services in their states and communities.

Stigma toward mental health may lead to social withdrawal and the perception of being devalued or discriminated against, which in turn can affect the self-esteem of patients and become a barrier to recovery. Individuals can also develop a sense of embarrassment and shame. Many social factors may mediate the presence of stigmatization toward patients in recovery, including but not limited to: negative beliefs of family members or support systems toward mental illness itself, social media influence and stereotypes related to mental health, negative attitudes of society in general, attitudes of a healthcare professional during crisis or emergencies, as well as structural discrimination experienced by the individual. There is limited evidence about the effectiveness of specific interventions to reduce stigma related to mental health. However, psychoeducation, contact with the mentally ill, stigma self-management, protest, and social activism, as well as legislative reform and advocacy, have been mentioned as potential interventions. Reducing stigma is crucial to decrease barriers during the recovery phase.

Recovered patients are capable of managing routines, work, school, independent living, and illness self-management without direct supervision by relatives or mental health professionals. That being said, it is strongly recommended that recovered persons sustain their connection to mental health services, even if this consists of only occasional “check-ins” with their treatment providers, given the increased vulnerability to relapse and stress sensitivity often experienced by individuals who have experienced serious mental health disorders. Refresher courses for patients’ emergency plans to implement relapse prevention are one mechanism to extend recovery for longer periods of time.

ASSESSMENT IN PSYCHIATRIC REHABILITATION

The assessment of persons with SMI involves a thorough and holistic assessment of a number of important domains with specific well-validated tools. The goal of any good assessment is to render an accurate diagnosis and then to suggest areas that can be targeted with specific interventions. The key to a comprehensive assessment of SMI is a thorough clinical assessment of the presence of symptoms, including the nature, frequency, intensity, and duration of particular symptoms. It should be noted that the management of certain symptom clusters (e.g., reduction of hallucinations and/or delusions) but not others (e.g., apathy, social cognition, and interpersonal skills) may not be specifically addressed by specific pharmacologic and behaviorally-based treatments. In addition, reduction of symptoms is not analogous to a “cure” for most individuals since neurocognitive and behavioral deficits in conditions such as schizophrenia may persist after symptomatic relief of positive symptoms. A number of symptom rating scales include the PANSS, the BPRS, and the Scale for the Assessment of Negative Symptoms (SANS). These instruments can provide useful and important information on symptom dimensions and provide a common basis by which to come to inform clinical and research diagnosis as well as to assess outcomes. This appraisal is vital as an initial step in creating a collaborative recovery plan.

As with many assessment instruments, interpretation of these measures depends on the operationalization and validity of specific symptom constructs as well as their ability to designate which cluster of symptoms meets the criteria for a particular psychiatric condition. It is important to take into account the fact that many psychiatric syndromes have overlapping features and differences in symptom presentation can be a function of the stage of illness, time of onset of a psychiatric episode, and the context and environment in which the patient is assessed. Many persons with SMI have comorbid psychiatric and medical disorders such as co-occurrence of SUD. Further specific endocrine, metabolic, and neurologic disorders may produce symptoms that mimic psychiatric symptomatology. In addition, an assessment of coping skills, daily living skills, housing arrangements, level of education and employment, family involvement, and social, sexual, and spiritual needs should be integrated into the holistic assessment of SMI.

One of the big challenges in the field is that controlled clinical trials often use relatively stringent inclusion and exclusion criteria that do not account for all of the comorbid psychiatric conditions, medical conditions, polypharmacy, and important mediating factors such as adherence, supported employment services (SES), environmental supports, and cross-cultural issues. As a result, it is increasingly important to ensure that findings obtained from placebo-controlled, randomized clinical trials generalize to individuals in different medical, hospital, and community mental health settings. While controlled randomized clinical trials may possess internal validity, the true test of an intervention is its effectiveness in real-world community settings.

Neurocognitive Symptoms

Cognitive assessment is a crucial component of the assessment of SMI, particularly in schizophrenia, given the number of impairments associated with the disorder and its challenging effects on activities of daily living and functioning. Neurocognitive deficits are thought to be a core feature of schizophrenia and often include emotional processing, perceptual disturbances, attention, sensorimotor integration, executive function, context processing, social perception, processing speed, and working memory. Up to 40% of persons with bipolar disorder may have completely normal cognitive profiles. In contrast, up to 75% of persons with schizophrenia perform below general population standards on neurocognitive tasks. Early identification of neurocognitive deficits in individuals living with schizophrenia is important as these deficits strongly correlate with chronic disability.

A tremendously positive development in schizophrenia research has been the development of the Measurement and Treatment Research to Improve Cognition in Schizophrenia (MATRICS) and Consensus Cognitive Battery (MCCB) for the assessment of schizophrenia. As a gold-standard assessment battery, the MCCB tests for ten cognitive domains take approximately 60 to 70 minutes to administer and allow researchers to standardize trials. The MCCB has not only been successful in research on schizophrenia but has also been able to differentiate Bipolar I and Bipolar II patients from controls. It has been recommended that because of the more subtle nature of cognitive deficits in schizophrenia, additional tests that should be considered (besides the MCCB) include the California Verbal Learning Test-II (CVLT-II). In addition, the Wisconsin Card-Sorting Task, Trails B, and the Stroop Color-Word task are all measures that should be considered. Moreover, a shorter (10-minutes) easily-administered battery, the Brief Cognitive Assessment Tool for Schizophrenia (B-CATS), has been developed to assist clinicians in the cognitive assessment of individuals living with schizophrenia, with proven good test-retest reliability and correlating 0.76 ($P < .01$) with the MATRICS battery.

An interview-based assessment of cognition specifically for schizophrenia is the Schizophrenia Cognition Rating Scale (SCoRS). The SCoRS assesses cognitive functioning based on interviews with both patients and their caregivers. The assessor then incorporates both sources of information to determine a final rating. Performance on the SCoRS has been found to be associated with both actual performance on cognitive tests and measures of real-world functioning. One study indicated that patients with schizophrenia who perform “normal” on cognitive testing do not indicate an association between cognitive performance and social or vocational functioning.

The challenge with any neuropsychological assessment is that there are confounding factors in SMI other than underlying putative brain damage that may contribute to poor performance. For example, poor motivation, sedation and other cognitive effects of medications, social anxiety, paranoia or hypervigilance, and interactions with the test examiner may have significant effects on test outcomes. In some settings, attention and motivation to perform may be so low that the neuropsychological battery with the Tests of Malingering and Memory (TOMM) or Green’s Word Memory Test (WMT) is augmented. It is important that any neuropsychological assessment that is performed is not in the acute stages of SMI. It is much more helpful to conduct neurocognitive evaluation after ample stabilization has occurred. There is a tendency to think that neuropsychological testing taps orthogonal, independent cognitive domains but deficits in memory and measures of verbal fluency may all be related to generalized cognitive slowing, attentional deficits, and reduced speed of processing. While there have been attempts such as the National Institute of Mental Health (NIMH) initiative (Cognitive Neuroscience Treatment Research to Improve Cognition in Schizophrenia [CNTRICS]) aimed to develop measures derived from cognitive neuroscience, with explicit links to known neural systems and psychopharmacology, the field is still hampered by a locationist notion of the brain where a function is thought to occur in specific brain regions (e.g., amygdala) rather than distributed networks of neuronal activity that involve multiple brain regions. This highlights the importance of relating neurocognitive function to functional measures such as fMRI and PET in order to identify working neural networks in the brain.

Social Cognition

Social cognition involves a variety of socially relevant domains, including emotion perception, social problem-solving, understanding social cues, and interpretation of others' attitudes and intentions. There is increasing evidence that negative symptoms of schizophrenia have an impact on both social competence and social outcomes but do not exert an influence on social cognition. However, social competence and social cognition have significant effects on real-world social outcomes. The result of the Expert Panel and Rand Survey identified four major domains of social cognition that include (a) emotional processing, (b) attributional style/bias, (c) social perception, and (d) theory of mind (ToM)/mental state attribution. Measures that the committee agreed upon for final inclusion in the battery to assess the aforementioned domains included the abbreviated version of the Ambiguous Intentions and Hostility Questionnaire (AIHQ), Bell Lysaker Emotion Recognition Task (BLERT), Penn Emotion Recognition Test (ER-40), Hinting Test, abbreviated version of Relationship Across Domains (RADs), Reading the Mind in the Eyes Test, The Awareness of Social Inferences Test (TASIT), and the abbreviated version of the Trustworthiness Test.

As part of the Social Cognition Psychometric Evaluation (SCOPE) study, the results of the final validation study showed that the BLERT, a test of affect recognition, the ER-40, and the Hinting Task (ToM) had the highest psychometric properties among a number of social cognition tasks and are the ones recommended for use in clinical trials. Meanwhile, the TASIT, Intentionality Bias Task (IBT), and Eyes Test showed weaker psychometric properties and remain in need of further study. On the other hand, the Mini Profile of Nonverbal Sensitivity (MiniPONS) and the Social Attribution Task-Multiple Choice (SAT-MC) showed poorer psychometric properties, and caution should be exerted when considered for clinical trials.

Nowadays, pharmacologic interventions may be used in conjunction with social cognitive training to facilitate the improvement of neurocognitive symptoms. Aerobic exercise has been found to have positive social cognitive effects and may be useful when introduced in conjunction with social cognitive interventions.

Communication and Social Skills

Deficits in metacognition, the ability to construct complex ideas about oneself and others, and the ability to respond to social and psychological challenges underlie many of the communication and social skills deficits found in schizophrenia. This mismatch between perceptions of oneself and the world and communication with others in the environment can cause considerable difficulties for an individual with schizophrenia. Impaired communication and language skills have been identified as common in schizophrenia, and it has been shown that individuals with schizophrenia have greater social skills deficits than those diagnosed with major depression or bipolar disorder. Those with schizophrenia appear to have social skills deficits that are intermediate.

SST is based on behavioral principles of modeling; shaping, rehearsal, and positive reinforcement are all important parts of successful training paradigms. SST aims to develop or improve social interactions, social performance, or interpersonal skills. It should be noted that SST has advocated for helping an individual interact with his/her world. Both social cognition and negative symptoms in schizophrenia carry the most variance in explaining real-world social outcomes. SST has a positive impact on improving the negative symptoms of schizophrenia. This suggests that targeting both social cognition and negative symptoms may be as important as teaching social skills to individuals. The problem with both social skills and expressive and receptive communication deficits in schizophrenia is that there is a complex interaction between social perceptions, integration of thinking about self and others, and behavioral outputs that can all serve to produce negative outcomes affecting social, vocational, and community life. It is likely that the most effective approaches are going to have to focus on the complex interplay between individual perceptual and social cognition deficits, how these interact with more complex metacognitive processes and help modify behavioral repertoires that will foster optimal real-world functioning.

Assessing Functional Outcomes

Broadly speaking, the goal of any psychiatric rehabilitation or remediation effort is to enhance and support optimal functioning in the environment.

Reaching milestones such as stable romantic relationships or full-time employment are not sensitive measures of functioning. Despite the considerable overlap, there are varying types of functions, including interpersonal communication, the ability to manage one's household affairs, managing one's finances, community affairs, and working in a vocational setting. For example, managing one's household affairs may involve arranging for transportation to the bank or supermarket and understanding bus, train, or subway routes. There are important decisions to be made on how to prioritize income, making sure that income is used for food, housing, and medication before it is allotted for other purposes. Persons must interact and effectively communicate with others and meet daily responsibilities in the community and the workplace. Understanding the individual's psychiatric condition, treatment regimen, adherence to treatment, natural social supports, contextual cues in the environment, and an understanding of a patient's strengths and limitations is critical to helping the individual achieve optimal functioning within the community. This requires assessment techniques that allow for appropriate targeted interventions and remediation strategies. Proper assessment allows for optimal treatment and psychiatric rehabilitation. These are not two distinct entities but rather a continuous effort to promote wellness and maintain optimal function in many contexts.

A critical distinction between functional capacity and functional performance is crucial. Functional capacity refers to the ability and the underlying nonsocial skills required to successfully perform activities of daily living in the community. Functional capacity can encompass a wide range of activities such as (a) the ability to count money or balance a checkbook, (b) having sufficient social cognition to understand implicit rules regarding social interactions or behaviors, (c) adequate social skills to successfully navigate a work or community environment, (d) requisite cognitive abilities such as intellect, memory, reasoning, language abilities to engage in meaningful home, community or occupational activities. Examples of functional capacity include balancing a checkbook, preparing a meal, understanding, completing work tasks adequately (i.e., taking medications as prescribed), and using the public transit system. If a person does not possess adequate functional capacity (requisite skills required for independent or even assisted living), then the focus of psychiatric rehabilitation has to be on attempting to build and foster those skills that will result in the greatest independence and quality of life. On the other hand, functional performance, while often dependent on underlying functional capacity, refers to the actual ability to consistently perform a variety of skills in a way that maximizes autonomy, quality of life, and the ability to cope with real-world demands. The functional performance then represents the actual performance of the individual in the interpersonal, social, financial community, and vocational domains.

Individuals with a psychiatric condition such as bipolar disorder may have an excellent underlying financial capacity, intellectual skills, social cognition, and awareness and be able to live independently and be gainfully employed. However, because of the episodic recurrence of a wide variety of mood symptoms, there may be certain periods where they may fail to adequately manage their manic, depressive, or mixed episodes and may mismanage finances, have difficulties meeting the demands of home, work, or family and be incapacitated despite their high premorbid levels of functioning. Individuals living with schizophrenia may have intact financial and adequate cognitive skills to manage to work and live independently in some settings. However, persistent difficulties with negative symptoms and social cognition can lead to problems that may negatively affect their ability to support themselves and their families. Primary and comorbid substance abuse can radically cause a patient to make poor choices and to allocate financial resources to their addiction or dependency, thus threatening their living situation. Psychiatrists are confronted with the unfortunate challenge that many unsheltered, socially impoverished, and disadvantaged individuals have underlying psychiatric conditions and lack proper support systems that could substantially help to improve their well-being and quality of life.

The distinction between functional capacity and general real-world functional performance is critical in that these constructs dictate the approaches that one will take toward assessment and subsequent management. Skill-building and other approaches are necessary to help increase functional capacity (i.e., via individual or small groups SST). However, the effectiveness of these approaches can only be seen when they form the building blocks to enhance functional performance (i.e., generalizing SST to real-world community and/or occupational settings). Thus, assessment of functional capacity and real-world performance are critical elements in psychiatric rehabilitation. Functional capacity and performance can further be subcategorized with regard to particular domains such as cognitive, financial skills and judgment, social cognition, social skills, and judgment that affect individual autonomy and quality of life. Further, specific types of functional skills required for everyday living may pertain to specific domains such as caring for one's self in the home, successfully interacting with the community, or learning and maintaining job-specific skills. This suggests that functional assessment strategies need to be tailor-made for each individual and display reliability (consistency of measurement) and validity (assessing the construct that needs to be measured).

Types of Functional Assessment. Functional assessment can be employed in a number of ways. The most direct method of assessing functional capacity is direct observation of the patient performing behaviors in the clinical setting. One widely used "paper and pencil" measure, such as the Performance-Based Skills Assessment (UPSA) developed by investigators at the University of California, directly assesses the individual's functional capacity with regard to finances, communication skills, household chores, transportation, and planning recreational and other activities. The advantage of such a measure is that it is easy to administer, has demonstrated reliability and validity, and can provide direct and quantifiable information on functional capacity.

Knowledge of deficits in functional capacity can be critical for initial assessment as well as response to treatment. However, a performance-based assessment may not always map onto the individual's performance in the community. In this case, a qualified informant such as a friend, family member, or healthcare provider can provide essential information based on repeated observations of the individual in the context of different environmental supports and contextual cues. Specifically, a reliable collateral informant can provide essential information that may simply not be available by performance-based functional assessment. However, the quality of the informant matters and an assessment of the frequency and nature of the relationship may be beneficial. If a collateral informant has little opportunity to observe the patient, has a cognitive, psychiatric disability themselves, or self-serving biases, their report may be of little value in providing useful functional information. While it is always important to obtain and respect the individual's evaluation of their real-world functional performance, it is important to note that in schizophrenia and other neuropsychiatric conditions such as Alzheimer disease (AD) and other neurodegenerative disorders, reports are often positively biased (i.e., the patient often reports a much higher level of functional performance than may actually be the case). Anosognosia, or the "inability to appreciate what one does not know," is a neuropsychological condition that is seen in traumatic brain injury (particularly within the right hemisphere), AD, and psychotic disorders such as schizophrenia. A 2020 study showed that overconfidence in a social cognitive emotion recognition task in participants with schizophrenia was a predictor of poorer performance on every performance-based task, including other social cognitive tests and measures of neurocognition.

As a result, it is often very useful for the clinician to compare the report of the patient and reliable informant and to also use performance-based functional assessment tools and rating scales. In addition, computer-based performance assessments have emerged, such as the Virtual Reality Functional Capacity Assessment Tool (VRFCAT). VRFCAT involves assessing function in a simulated virtual world, including tasks such as: preparing a shopping list, riding a bus, shopping in a store, and managing money. One study has shown that it is feasible to use technology-based functional capacity assessment protocols with older adults and patients with schizophrenia by conducting the assessment on a touch screen computer, with a battery of tests including ATM banking/financial management, prescriptions refill via telephone/voice menu system, and forms completion (simulating a clinic and patient history form). However, it is important to note that an individual's ability to complete these skills in a simulated and controlled environment differs from completing these skills in day-to-day life. An individual with prominent negative symptoms of schizophrenia may struggle with avolition and anhedonia and thus would have a lack of motivation for completing such tasks in the real world. Defeatist attitudes in individuals with schizophrenia have been shown to affect variance in negative symptoms, as well as neurocognition and functional outcomes. It is important to assess the individual's motivation in engaging in these rehabilitative assessments and interventions.

Functional Assessment Scales. In addition to the UPSA, the performance-based measure of functional capacity, a study also notes important scales for functional capacity such as the ILS and Test of Adaptive Behaviors (TABS). Everyday functional rating scales selected by the RAND expert panel include the Independent Living Skills-Survey

(ILSS), Specific Levels of Functioning Scale (SLOF), Life Skills Profile (LSP), Birchwood Social Functioning Scale (SFS), Social Behavior Schedule (SBS), and Heinrichs-Carpenter Quality of Life Scale (QLS).

The most widely employed measure of functional capacity, the UPSA, is a particularly compelling scale of functional capacity that has shown correlations of 0.6 to 0.7 with neurocognition in a number of studies. The USPA requires specialized personnel for administration. It includes simulations of everyday activities of daily living such as communication (i.e., dialing the telephone to schedule a physician appointment, obtaining and dialing a number from a telephone operator); comprehension/planning (reading and planning a recreational outing such as to the beach on a hot sunny day); finance (counting currency, making change, and paying a bill); household management skills (e.g., shopping for grocery items), and transportation (using a bus schedule in planning a trip and understanding charges and obtaining route information). Some versions of the UPSA include a medication management subtest and are referred to as the UPSA-II. USPA-B is a shorter version of this instrument that focuses on communication skills and finances.

The SLOF relies on self or informant reports but is especially useful when employed by a high-contact clinician. The scale taps the following domains: Participation in Community and Household Activities, Interpersonal Relationships, Work Skills, Self-Care, Physical Functioning, and Socially Acceptable Behavior subscales.

The UPSA has the advantage of being an objective performance-based functional measure and is preferable to self-reports of patients who often overestimate their abilities or questionable informants. Critics of the UPSA maintain that the UPSA measures tap functional behaviors but that they are more psychometrically similar to cognitive measures. There are contextual cues in the real-world environment that dictate real-world functional performance apart from demonstrating capacity in contrived clinical and laboratory settings. Measures such as the SLOF are most effective when used with informants but may in some cases be susceptible to reporter biases. The SLOF and other functional rating scales are typically most effective in the hands of a high-contact clinician who knows the patient well and can weigh informant and patient reports against his/her own clinical judgment. While the SLOF has been extensively validated with schizophrenia patients, studies have shown that 64% of patients with bipolar disorder showed evidence of deficits in one or more SLOF domains. The UPSA-1, UPSA-II, or UPSA B has been employed with a large number of patient groups, including those with major depression, bipolar disorder, and schizophrenia. Importantly, the instrument has also been employed in diverse cultural and language groups. A systematic review found that SLOF had the strongest observed correlation with the UPSA.

Other important scales in psychiatric rehabilitation include the Maryland Assessment of Social Competence (MASC), a structured role-play designed to assess social skills. Other scales use time-sampling techniques consisting of numerous observations of patient social behaviors, such as the Time Sample Behavioral Checklist (TSBC), Clinical Frequencies Recording System (CFRS), or Staff-Resident Interaction Chronograph (SRIC) but are usually only appropriate for institutional and residential treatment settings since these involve extensive ratings by staff members.

SPECIFIC APPROACHES

Cognitive Remediation in Community and Occupational Function

Neurocognitive deficits are core features of schizophrenia, and moderate to severe cognitive impairments are present in the vast majority of cases. CR may lead to small to moderate improvements in negative symptoms and social functioning, in addition to cognition. CR can be especially beneficial for persons experiencing subjective cognitive symptoms with schizophrenia and for individuals experiencing vocational challenges. This approach generally starts with simple information processing tasks, and then progresses toward more complex tasks such as targeting working memory and planning.

Cognitive remediation therapy (CRT) is an intervention that enhances cognitive performance in individuals with schizophrenia. However, other psychosocial interventions may be needed to improve functional outcomes. In the last two decades, studies have focused on identifying psychological and nonpsychological approaches to enhance social cognitive interventions and improve functioning. Even early in the course of psychotic disorders, social cognitive interventions can be helpful, and evidence shows that social cognitive deficits are present during the prodromal phase of individuals at high risk of developing psychotic disorders. As not all individuals benefit from social cognitive training, combining this approach with psychopharmacology may be promising.

The most commonly used measures are memory scales such as the Rey Auditory Verbal Learning Test (RAVLT) or CVLT-II. Executive function is often measured by the Wisconsin Card Sorting Test (WCST) or Trails B (although this measure taps many aspects of neurocognitive function) or measures of the Delis-Kaplan Executive Function System **(**DKEFS). Digit symbol of the WAIS-IV is a good measure of processing speed, as is Trails A. Examples of widely used neurocognitive batteries include the MATRICS MCCB, the Brief Assessment of Cognition in Schizophrenia (BACS), and Repeatable Battery for the Neuropsychological Assessment of Schizophrenia (RBANS).

When combining CR with functional skills training, better results in community living skills occurred than with functional training alone. An important review indicated that poor neurocognitive function had significant effects on vocational and occupational status within the community setting. Subsequent investigations revealed that CR plus SES enhanced positive employment outcomes, whereas other studies have not shown such effects. The notion is that training component cognitive abilities in the hopes that they will generalize to specific real-world behaviors may be less important than directly training target behaviors of interest. As an example, consider an adult with schizoaffective disorder who is working in a supported occupational setting. One approach might be to train specific cognitive component abilities in the hopes that they will generalize to the work setting. An alternative approach would be training those skills required for job-related performance. For example, CR strategies would specifically target actual job-related activities such as organization, strengthening procedural memory for certain role activities, and employing strategies to monitor performance. This targeted functional training would involve the cognitive aspects of the skills related to employment but directly integrate this training in an integrated manner and in a manner that would more likely generalize to the employment setting. Some studies have indicated that CR can be associated with neuroadaptation, though it is unclear if there are other factors influencing these results and if results persist with time.

Rehabilitation of Social Cognition

There has been an increased interest in moving beyond merely framing core features of schizophrenia in terms of positive and negative symptoms and neurocognitive impairment. There has been emerging evidence that deficits in social cognition can also be considered core and stable features of schizophrenia. Social cognition pertains to the perceptions, beliefs, and interpretation of other people's behaviors. Poor social cognition can significantly impair a person with SMI to appropriately respond to others in their environment. Green and others described five major aspects of social cognition; (1) ToM generally refers to an individual's ability to infer the beliefs and perceptions of others; (2) Social knowledge consists of the understanding of rules and conventions that underlie social behavior and guide social interactions; (3) Social perception is the ability to recognize general rules concerning roles and societal rules; (4) Emotional processing involves the experiencing and use of emotions and has been linked with emotional intelligence; and (5) Attributional bias involves attributing causality to both positive and negative outcomes. Each of these components is critically important in understanding how an individual relates to others in the community and their vocational performance. It should be noted that deficits in social cognition are not only observed in those with schizophrenia but also in individuals with bipolar disorder and, to a lesser extent, those with major depressive disorder.

There is increasing evidence that social cognition accounts for far more variability in community function than neurocognitive abilities. Moreover, a meta-analysis of studies on social cognition revealed that social cognitive training procedures have relatively large effects on emotion recognition, small to medium effects on measures tapping ToM effect, and no effects on attributional bias or social perception. One of the most important findings in this study is that these kinds of techniques have a moderate to large effect on community functioning. However, there may be less of an effect on higher-order social cognitive functions, which may improve more by using virtual reality such as the RC2S (CR of social cognition), which involves navigating a computerized character through situations that require emotional processing and learning contextual cues.

A 2018 meta-analysis of neuroimaging studies examining brain activation during facial emotion recognition and ToM tasks in patients with schizophrenia found neural-related circuit disruptions (i.e., reduced recruitment of the right insula, anterior cingulate and medial prefrontal cortex, and increased activation in the bilateral parietal cortex) leading to complex impairments in social cognition. Later on, a 2020 meta-analysis further described neural correlates known to play a role in social cognition of those with schizophrenia (i.e., bilateral anterior insula, right temporoparietal junction, left amygdala, and dorsolateral prefrontal cortex), suggesting that these brain areas should be studied as a potential target for therapeutic interventions in this population. Other small studies examining effects of social cognition intervention found neuroplasticity changes, including a reduction in grey matter loss, increase in regional brain activity, and decrease in alpha-range EEG activity, though these studies require to be replicated.

Cognitive-Behavioral Therapy

CBT is a type of psychotherapy based on principles of conditioning, learning, and cognition. As applied to schizophrenia, CBT engages patients collaboratively, challenging their interpretations of events or experiences. In schizophrenia, CBT aims to reduce the intensity of delusions, hallucinations, and related anxiety, to develop more adaptive behavior, and to encourage engagement of the person in relapse prevention. In many cases, the reduction in anxiety that accompanies modified attributions regarding voices leads to a reduced frequency and intensity of hallucinations. Individuals who are able to reframe or find alternative explanations for their positive symptoms can experience relief from these symptoms. If an individual resists challenging these symptoms, the CBT provider can encourage the individual to identify coping mechanisms to reduce distress related to these symptoms. In the case of negative symptoms of schizophrenia, CBT is often used to challenge anhedonic beliefs, schedule activities, and administer self-rewards for increasingly engaging in pleasurable activities. CBT can be provided in individual or group settings and works best with patients who are willing to actively participate in treatment, often as the result of distress from symptoms and/or at least minimal insight into the abnormal nature of their experiences.

A 2014 meta-analysis of 14 studies including 1,484 patients found that compared to other adjunctive measures, CBT showed a significant reduction in positive symptoms. The specific symptoms alleviated with adjunctive CBT include delusions, distress, or delusions related to auditory hallucinations, paranoia, and negative symptoms. Improvements in distress related to auditory hallucinations and delusions were maintained at follow-up. A more recent meta-analysis of CBT for schizophrenia conducted in 2018, including 33 studies with a total of 1142 participants with schizophrenia and positive symptoms, measured response rates to CBT by the degree of improvement. In this meta-analysis, 44.5% of patients exhibited a 20% (minimally improved), and 13.2% of patients exhibited a 50% (much improved) reduction of overall symptoms. However, the degrees of improvement reported on positive symptoms showed 52.9% (minimally improved) and 24.8% (much improved) in patients.

It seems that CBT may help patients presenting with psychosis. However, the effects may be small to moderate. Further research is needed to assess the efficacy of CBT for schizophrenia on social functioning, quality of life, relapse prevention of psychotic episodes, insight, and other outcomes. Meanwhile, it is worth noting that in addition to problems uniquely associated with psychotic disorders, various forms of CBT are effective for addressing generalized anxiety, panic, social anxiety, depression, obsessive-compulsive symptoms, and SUD. These problems may co-occur with chronic psychotic disorders, and there is no reason to believe that CBT interventions are any less effective in treating them in people with schizophrenia than in the general population.

Most patients with schizophrenia are able to engage in CBT despite exhibiting acute psychosis and cognitive deficits, as long as they are somewhat motivated to engage in CBT. Motivated patients typically demonstrate good treatment responses, whereas unmotivated patients often do not respond or drop out of treatment. A major challenge is to find ways to engage patients exhibiting first-episode psychosis in CBT. Often, more supportive efforts are needed to engage first-episode patients in the treatment system prior to initiating CBT.

Social Learning and Social Skills Training

The social learning program (SLP) is a comprehensive, integrated set of learning-based techniques (typically including a token economy) and skills-training activities. In most cases, an SLP is delivered within the context of a residential facility, usually for patients with severe and chronic behavioral disabilities. A key feature of the SLP is that all staff members on all shifts are trained to structure their interactions with patients in specific ways during all waking hours. Research indicates that SLP is the most effective form of inpatient treatment for people with schizophrenia, including the so-called “treatment-refractory” patients. The SLP has demonstrated effectiveness with a wide range of people with disabilities in a variety of settings (e.g., state and private hospitals and maximum security forensic hospitals). The components of the SLP form an extremely positive teaching environment that assists clients in developing adaptive behaviors and skills relevant to successful return to the community. Contemporary versions of this approach incorporate skills-training technologies, psychiatric rehabilitation techniques for engaging clients, CBT, vocational rehabilitation, cognitive rehabilitation, and substance abuse treatment.

A guiding assumption of the SLP is that all persons with severe mental disorders, no matter how severe the impairments, can learn new behaviors and skills and, therefore, progress to less structured environments. To promote behavior change and skill acquisition, the SLP incorporates a wide variety of techniques based on fundamental learning principles. Differential reinforcement forms the basis of many of the procedures of the SLP. Staff at all levels and disciplines are highly trained and carefully supervised in the timely and consistent delivery of verbal praise, positive social attention, and material reinforcement for adaptive behaviors and the application of extinction or response-cost techniques for bizarre, aggressive, or rule-violating behaviors. Effective SLPs deliver much more positive reinforcement than extinction or response costs. The result is a highly reinforcing, positive, and supportive environment.

Although most comprehensive SLPs include some sort of token economy or point system to deliver feedback and behavior-related consequences, some use individual behavioral contracts, contingency management plans, or social reinforcement alone. However, in all well-designed SLPs, specific objectives and goals of clients are individualized, as are the specific interventions for assisting them with acquiring the skills necessary to accomplish these goals/objectives. Another key feature of all effective SLPs is that, as patients begin to demonstrate improvements in behaviors, there is a planned and systematic withdrawal of tokens or points and an emphasis on generalization training so that clients will be able to apply acquired skills and knowledge successfully in “real-life” community settings under more natural, primarily social reinforcement conditions.

An effective SLP is based on a wealth of data that is generated during all waking hours by all staff, using a number of observational rating procedures (described in the section on assessment). The availability of data on all critical behaviors (e.g., grooming, attendance at groups and activities, social contacts, and aggressive behavior) allows for sophisticated data-driven treatment planning. Moreover, the ability to demonstrate specifically to patients why their privileges or other consequences of their behavior are occurring and what needs to change, and how much to receive different consequences is a powerful tool. In effect, this type of data-driven system serves to instill responsibility for behavior change in the patient, instills a sense of agency and mastery regarding behavior change, and reduces the institutionalized and dependent attitude that staff arbitrarily determine privileges, which is so often found in state hospital settings. Moreover, as demonstrated in a recent study, patient satisfaction with treatment is often high in SLPs.

Given the complexity, specificity, and range of procedures involved in the SLP, staff training is of paramount importance. All staff members are involved in extensive initial and ongoing training, using both didactic instruction and in vivo practice. Competency-based supervision is provided through regular performance feedback, using observational data on staff-patient interactions and structured supervisory observations.

Another important feature of SLPs is the focus on the generalization and maintenance of gains after program discharge. As patients acquire skills and develop goals for community living, they are provided with opportunities to apply these skills and pursue their goals in community settings. After discharge, declining contact aftercare is provided. Some SLPs arrange to train staff at community residential facilities to maximize the maintenance of gains after discharge.

SLPs have traditionally been provided in long-term treatment units. Recently, however, modifications of the full program have been tried in other settings, such as acute inpatient units and community-based residential settings for outpatients with SMI, with demonstrated success.

Illness/Wellness Management Skill Training

Gaining the ability to manage one’s psychiatric illness is central to the rehabilitation and recovery perspective. In the rehabilitation and recovery literature, skill training in illness/wellness management has gradually been differentiated from related social, and living skills approaches, reflecting a growing recognition that specialized skills are needed to self-manage psychiatric disorders, comparable to skills needed to self-manage physical conditions such as diabetes. When providing persons with SMI the knowledge and skills, they are empowered to manage their own symptoms, make informed decisions about their treatment plans, and identify their recovery plan. People learn about the episodic and persistent symptoms of their illness, the relationship between symptoms and functional impairments, pharmacologic options and other behavioral techniques (e.g., relaxation and stress management) for controlling symptoms, medications side effects, identification of “warning signs” of an impending relapse, creating a relapse prevention plan, skills to collaboratively communicate with the rehabilitation team, mental health providers and family who can support their recovery journey, and various other aspects of their disorder and its management. Behavioral skills indirectly relevant to disorder management include, for example, the assertive skills necessary for dealing with the doctor and the doctor’s receptionist in getting an appointment for a medication visit. Integrated Illness Management and Recovery (I-IMR) programs target patients who have psychiatric disorders and comorbid medical conditions. Wellness self-management includes directing individuals with issues relating to lifestyle choices, nutrition, physical activities, relationships, spiritual and pleasurable activities.

Several developer groups have packaged illness/wellness management skill training materials for testing and dissemination. A number of original studies and reviews confirm the effectiveness of skill training focused on illness/wellness management for improving adherence to treatment in people who live with SMI. The SAMHSA has produced packages for public dissemination that fall under this category, including What Individuals in Recovery Need to Know About Wellness, Illness Management, and Recovery, and Medication Management Approaches in Psychiatry. Both packages include materials for all participants in the illness/wellness management process, including the person in recovery, physician, other service providers, family, and friends. The Agency of Healthcare Resource and Quality (AHRQ) created a Self-Management Support Resource Library with training material for providers as well as patient material on self-management. These resources can be accessed on AHRQ’s website: https://www.ahrq.gov/ncepcr/tools/self-mgmt/home.html

Illness/wellness management training for people with schizophrenia benefits from relapse prevention and related techniques. Relapse prevention programs work with individuals to identify environmental stressors that can trigger warning signs of relapse, develop steps that can be taken to prevent relapse, and teach individuals stress management techniques. Well known for its application in substance abuse, many of the techniques of relapse prevention are well suited to the episodic nature of the lived experience of people living with schizophrenia, the role of stress in precipitating psychotic symptoms, and the important role of the recovering person in managing those episodes. The original application of relapse prevention is also of interest and should be further studied, given that people with schizophrenia often have substance abuse problems as well. Peer involvement is also especially relevant to illness/wellness management.

Supported Education

Supported education prepares people with psychiatric disabilities to achieve educational goals in an academic setting in a person-centered approach, including starting college or continuing interrupted college education due to mental health issues. A retrospective study examining medical records of 114 patients with the first episode of psychosis (FEP) found that 82% of individuals enrolled in college experienced interruptions in their education following FEP. Supported education can help forge a path for individuals with SMI to develop future careers or engage in meaningful work. A randomized controlled trial in 2017 found that a comprehensive, team-based treatment program that includes supported employment and education for individuals following FEP was associated with greater improvement in work or school participation.

Supported education addresses ways to overcome obstacles related to achieving educational success, such as improving academic skills and problem-solving, bolstering self-confidence, and engaging in career development. Every college has its own policies regarding disability support services, with accommodations varying depending on the individual’s needs. Registering with the college’s disability resource office, providing documentation of the diagnosis, prior and requested academic accommodations, and collaborating with the college disability resource center are some of the steps needed to be taken by individuals with SMI to obtain supported education.

Many models of supported education exist, including contained classrooms, onsite support, and mobile support. In the mobile support approach, a counselor meets one-on-one with a student to tailor an individualized plan to maximize academic success. This may include assistance in accessing services already in place in the educational setting, help with locating and using school social and recreational services, preparatory coursework, case management support, ongoing support and check-in meetings at the local student center, study support, visits to the campus library, linkage support to other campus services, and individual counseling (didactic, supportive, and/or exploratory). Other models of supported education include didactic group meetings in a classroom setting focusing on study skills, supportive group meetings, and the provision of standard study guides. Evidence from these programs suggests that distress levels are higher in people with schizophrenia than in other students. This should lead to further efforts to introduce stress management techniques into supported education activities for patients with schizophrenia. In addition, some rehabilitation programs offer wellness and resilience training, as well as academic coaching for individuals with SMI who are on college leave.

Sex Education

Many individuals with SMI aspire to and achieve meaningful education, work, and enjoy mutually supportive family and intimate relationships. The topic of intimacy and sexuality has been given the least attention in this population by mental health professionals. Surveys have discovered that 60% to 70% of adults with SMI report being sexually active in the last year, with approximately 30% reporting two or more partners. Persons with SMI are more likely to be involved in risky sexual behaviors, including inconsistent condom use, multiple sexual partners, and transactional sexual acts. In addition, some psychotropic medications are associated with sexual side effects. Persons with chronic mental illness are also more likely to experience intimate partner violence as well as sexual exploitation.

Sexuality and sexual expression should be recognized in all individuals living with chronic mental illness. The World Professional Association for Transgender Health (WPATH) has created a standard of care guideline for health professionals caring for transgender and gender diverse, including guidelines on psychological well-being, social support, and individual fulfillment. Sexual health education needs to be tailored for lesbian, gay, bisexual, transgender, queer, intersex (LGBTQI) individuals. Peer-to-peer support can be beneficial in sexual education.

Clearly, sex education should be an integral part of a comprehensive rehabilitation program. The current impetus for increasing patients' sexual knowledge derives in part from the alarmingly high rates of HIV infection and AIDS found among individuals with SMI. Not surprisingly, the majority of sex education programs have been designed to increase patients' awareness of the risk of infection, dispel misinformation and stereotypes, and provide the knowledge and skills needed to decrease their chances of becoming infected. A meta-analysis examining prevalence data of blood-borne infections in people with SMI found that people with SMI are at risk of blood-borne viral infections, but due to methodologic limits, these prevalence rates may be overestimated. Other contributing factors include low socioeconomic status, substance use, and sex. Emphasizing teaching techniques that use procedural learning and memory can mitigate any cognitive disabilities that may impact learning. In psychiatric rehabilitation, implicit or procedural learning is enhanced by video, and live demonstrations termed social modeling. Other techniques that build on procedural learning and memory are role-playing, interacting with a computer as in computer games, using pictures and attractive graphics to amplify written information, and engaging in repeated practice.

These educational methods can also be used for sex education programs that have broader goals than simply teaching persons with serious and persistent mental illness how to reduce their chances of becoming infected by HIV. Some of the educational objectives that comprise more ambitious and enlightened efforts in this realm include the following:

- Increasing patients' knowledge and comfort about sexuality
- Encouraging patients to identify and clarify their values and attitudes about sexuality
- Informing patients about alternative methods of birth control
- Teaching patients decision-making skills regarding sexual activity
- Overcoming medication-related sexual dysfunction and preventing deterioration or cessation of sexual activity
- Improving intimacy skills
- Imparting basic education on sexually transmitted diseases
- Instructing patients in proper condom use

COMORBID SUBSTANCE USE DISORDERS

The field of psychiatric rehabilitation is confronted with the need to identify and treat SUD as epidemiologic data show high prevalence rates among individuals with concurrent SMI. SUD have been associated with medication nonadherence, underachievement, decreased work productivity, poor health, neuropsychological impairment, social dysfunction, and violence, among other negative biopsychosocial effects. Prospective studies have shown that treatment outcomes, hospitalization rates, housing stability, and functional status are worse among patients with dual disorders. Studies have also shown that problems related to substance use tend to persist over the long term among patients with SMI. Lifetime treatment or help-seeking behavior is uncommon, particularly among those with psychiatric comorbidity. Thus clinicians are encouraged to be proactive with assessing for SUD to mitigate the negative impact on successful recovery and community adjustment.

Historically, individuals with SMI such as schizophrenia and co-occurring SUD received treatment for one disorder but were excluded from the other. Eventually, distinct and parallel treatment programs emerged; however, treatment outcomes were poor using this model. As a result, integrated treatment models combine substance abuse and mental health interventions in one clinical program. This model provides comprehensive outpatient dual disorders interventions as well as integrated residential treatment programs. In integrated treatments for patients with dual disorders, mental health treatments, and substance abuse treatments are brought together by the same clinician, or team of providers, in the same program to ensure that the patient receives a consistent, specific, and holistic explanation of illness and a coherent prescription for treatment rather than a contradictory set of messages from different providers. Integrated treatment aims to improve collaboration between treatment providers, eliminate the patient’s burden of attending two separate programs, and remove financial and other barriers to access and retention. Comprehensive programs have frequently included not only standard mental health interventions, such as medication monitoring and support services, but also assertive outreach to engage patients in treatment; intensive case management; trauma interventions; housing supports; and individual, group, and family substance abuse counseling.

Motivational interviewing, as well as CBT, are often utilized in patients with comorbid substance use and chronic mental illness. Harm reduction such as needle exchange services and pharmacologic therapy such as opioid replacement therapy can be incorporated as well on an individualized basis. Relapse prevention, which is often included in these approaches, focuses on preventing exacerbations of both mental illness as well as substance use relapse. Literature in this area shows that long-term treatment is associated with better overall outcomes. Research efforts are still being made to test and refine individual components and combinations of integrated dual-diagnosis treatments. As with all treatment, effective interventions targeting substance use should be individualized to address personal factors and the stage of motivation.

TOWARD MORE INTEGRATIVE MODELS OF CARE

Current psychiatric rehabilitation extends far beyond previous psychosocial models that were added to medication management and other somatic therapies. Psychiatric rehabilitation today is an active, collaborative, and person-centered endeavor, which necessitates a strong therapeutic relationship, trust, and collaboration between the patient, family, and multidisciplinary treatment team. Excellent treatment is predicated by using state-of-the-art and empirically validated assessments. While neurocognitive deficits may be pervasive in many types of schizophrenia, persons with bipolar or unipolar affective disorder may have less but still significant impairment in this area. In some cases, comorbid substance abuse disorders can further impair already pre-existing cognitive deficits. Equally important is the accurate assessment of functional capacity (based on performance-based tests) and, most importantly, real-world functional performance. Functional performance cannot be limited to merely higher- and lower-order activities of daily living but must also encompass social and vocational functions. There is also increasing evidence that deficits in social cognition and meta-cognition create considerable stress for individuals with schizophrenia beyond typical memory impairments, slow cognitive processing, and other neurocognitive deficits. As previously discussed, there is ample literature to suggest that improving communication skills, enhancing social skills, and behavioral goal attainment are all effective means to help the individual cope with stressors that might increase the likelihood of relapse.

This chapter has focused on empirically oriented approaches that can help in these efforts. As previously mentioned, it is of essential importance for both the patient and the treatment team to (a) identify targeted short-term and long-term goals that are both operational and obtainable, (b) plan interventions and build supports that are appropriate to a person's stage of recovery, (c) build coping strategies and stress management techniques that will reduce the chances of relapse, and (d) foster a collaborative treatment milieu involving the patient, family, and care providers.

Every person with SMI is a unique individual. While evidence-based approaches can provide guidance in the selection of the best instruments and interventional tools, this can never be done in isolation and without knowledge of the person's strengths, weaknesses, resources, support, and unique personality and environment. The best chances for optimal recovery and stabilization are through a multimodal approach that encourages adherence to medication and targeted treatment goals, stress management, and coping techniques, as well as developing optimal environmental supports.

SMI conditions are like many other chronic medical conditions that need constant attention and management. However, unlike many physical ailments, persons with SMI still have to manage additional stigma and lack of understanding afforded those with chronic medical and neurologic conditions. The most effective interventions will be those with the most empirical support, targeting the many different aspects of deficits in SMI (including but not limited to social isolation, deficits in social cognition, problematic meta-cognition, functional and vocational deficits, as well as problems with communication and social skills). Focusing solely on these targets without recognizing the importance of contextual cues and social supports risks fragmenting care.

Psychiatric rehabilitation is based on providing hope, self-empowerment, resilience, and recovery outlook and works to provide a patient-centered approach for individuals with psychiatric disabilities to accomplish their desired goals. There needs to be continued emphasis on more accessible, inclusive, culturally sensitive, integrated, and comprehensive models of care. Patients deserve no less.

56.7 A Sociocultural Framework for Mental Health and Substance Abuse Service Inequities

Margarita Alegría, Ph.D., Bernice A. Pescosolido, Ph.D., Kiara Alvarez, Ph.D., and Glorisa Canino, Ph.D.

The Institute of Medicine defined disparities in health care as "racial or ethnic differences in the quality of healthcare that are not due to access-related factors or clinical needs, preferences, and appropriateness of interventions." Responding to an important gap in the definition, the National Institute on Minority Health and Health Disparities expanded the definition in 2019 to include "a pattern of poorer health outcomes, indicated by the overall rate of disease incidence, prevalence, morbidity, mortality, or survival in the population as compared with the general population" and defined "racial/ethnic minorities, socioeconomically disadvantaged populations, underserved rural populations, and sexual and gender minorities" as those more likely to experience the disparities. Although reports since 2000 have strengthened public concern about glaring discrepancies in patterns of health service use and outcomes for racial and ethnic minorities in the United States, there has been limited progress in disparities reduction from 2000 to 2018.

Most entrenched disparities continue to be associated with the patient's race, ethnicity, and income profile. Ignoring these nonmedical factors represents a lost opportunity to eradicate the augmented age-adjusted mortality and increased burden of disease for minority populations. Despite the attention focused on health services disparities, particularly in view of demographic projections suggesting that ethnic/racial minorities will become the majority of the U.S. population by 2045 and by 2020 for children, we lack strategic approaches that match the complexity of the problem. Understanding the policy, social, and cultural factors that account for and reduce these disparities provides guidance for crafting effective individual interventions and systemic policies. Without frameworks and models, implementing the science-to-services translation called for by the National Institutes of Health is challenging.

To date, numerous conceptual frameworks have attempted to chart the potential causes of mental health service disparities. Most are based on the understanding that disparities in mental health and mental health care have no single underlying cause and that mechanisms likely vary across racial/ethnic groups and geographic contexts. Many scholars argue that the *fundamental causes* of health service disparities emerge from macrosocial factors such as historical and contemporary structural racism. Structural racism refers to “the totality of ways in which societies foster racial discrimination through mutually reinforcing inequitable systems (e.g., in housing, education, employment, earnings, benefits, credit, media, health care, and criminal justice, etc.) that in turn reinforce discriminatory beliefs, values, and distribution of resources.” Given the entrenchment of structural inequities in resources, policy, and practice, many scholars argue that a targeted focus on structural racism offers a direct and effective approach to finding a solution to health service disparities.

Additionally, some frameworks detail a small set of factors related to a single, particularly important, intermediary mechanism (e.g., residential segregation or employment) of health service disparities. Others seek to provide an overview of a broad range of possible mechanisms. A basic critique of service disparities frameworks is that too many have centered closely on individual-level mechanisms (i.e., supportive social relationships, family networks) and individuals’ responses to those circumstances (i.e., optimism, personal agency), which impact psychosocial reserve capacity and cognitive-emotional processes. These models tend to be reductionistic, failing to incorporate dynamic, system-level factors or consider reciprocal effects of different interventions, the context of dynamic reciprocal relations, or issues such as the availability of resources or services in the area. These system forces are vital to grasp the essential issues and to design system interventions. However, targeted factors should be those that matter substantially, are modifiable, and advance the science and public policy practice. Building from past theoretical and empirical work, this chapter updates a culturally informed, complex, population health systems framework for mental health and substance abuse service disparities which integrates a new definition of health care inequities.

In our effort to integrate sociocultural elements into a health service inequities frame, our definition of health care inequities or disparities refers to *racial and ethnic differences in access, health care quality, or health care outcomes that are not due to clinical needs or the appropriateness of treatment* and that *are a result of systemic, avoidable, and unjust social and economic policies and practices that create barriers to equity in mental health and substance abuse treatment services and outcomes.* Disparities occur across many dimensions, including race/ethnicity, socioeconomic status, age, location, gender, disability status, and sexual orientation. Patient preferences are also included as potential sources of disparities since they do not stem from "undue differential treatment on the basis of race and ethnicity." Past experiences and availability of services patterns might influence racial and ethnic minorities' preferences in treatment. Thus, preferences cannot be disentangled from people's available options in care or from health literacy factors and can contribute to inequities.

This approach to understanding disparities in service delivery emphasizes that sociocultural processes refer not only to race/ethnicity as a particular set of values, norms, and beliefs but also to the historical and concurrent circumstances and experiences leading to a group's social, economic, and political status. In addition, culture creates repertoires or "cultural toolboxes" that provide accepted "go-to" ways to behave, including how to respond to health problems. To understand the relationship between culture and health, a simplistic view of culture or cultural differences cannot work. Cultural processes are fundamental threads connecting communities, health systems, providers, and patients. They "veil" the entire complex system that deals with population health. Nowhere in the Sociocultural Framework (SCF) is the nature and operation of "culture" partitioned in a separate box or, even more importantly, proxied by sociodemographic categories. Racial, ethnic, and national categories are just proxies for markers of culture, pre- and postimmigration histories, and social and economic stratification, and they should be acknowledged as such. Since each individual has a profile of statuses, not just one, that could be subject to discrimination (e.g., member of a minority group, identifies as LGBTQ+, and is an immigrant), understanding and addressing their joint effects on mental health, substance use, treatment, and outcomes is complicated. When researchers are trying to reflect intersectionality (i.e., the convergence of multiple devalued statuses) rather than including an ever-expanding set of interacting statuses, Lamont and colleagues suggest focusing on cultural capital and cultural processes that sustain and reproduce societal and health inequities.

THE SOCIOCULTURAL FRAMEWORK: A COMPLEX, POPULATION HEALTH SYSTEMS APPROACH

Many of the recent agenda-setting reports in medicine see many contexts implicated in the cause, treatment, and outcomes of health and disease for individuals, providers, and societies. In many ways, seeing the relevance of everything from genetic risk to national health care policies is not new. From Bronfenbrenner's early ecologic systems theory to the current popularity of socioecologic models, the idea that different contexts matter for human growth, development, and well-being has become the "metaphorical blueprint" for much of basic and translational science. There is a general acceptance that the "environment" or the "environmental context" in its many guises "gets under the skin" and "inside the mind." What is novel here, and often missing in these standard models, is the recognition that much of what happens across these contexts results from the active forces that operate at their borders. Context here is composed of two types: across-level contexts (e.g., place or geography, health care organization, and individuals) and across-system contexts (the community and the health care system). Complex systems theory offers the view that these across-level and across-system interactions tend to persist over time, adapt to changing circumstances, and, as a result, are difficult to alter by addressing only one level or one system. Thinking through how major contexts meet, clash, cooperate or otherwise interact across levels and systems provides novel insights for critical, potential levers of change. Even more importantly, without establishing what happens at the touchpoint of major levels and systems, unintended consequences are likely.

As depicted in Figure 56.7–1, the Socio-Cultural Framework (SCF) for Mental Health and Substance Abuse Service Inequities has three essential elements—systems, levels, and interacting mechanisms. Two key systems in the complex population health system that can produce disparities or buffer inequities are the health care system and the community system. Each operates at three levels—the societal level (larger policy or environmental contexts), the organizational level (formal organizations or lay sectors), and the individual level (provider or patient). At each level, these contexts interact or interface to produce the fundamental mechanisms of inequality and bias that cumulate to inequities in health, health care, and quality of life.

FIGURE 56.7–1. A sociocultural framework for mental health and substance abuse service inequities. (Adapted from Alegria M, Pescosolido BA, Williams S, Canino G. Culture, race/ethnicity and disparities: Fleshing out the socio-cultural framework for health services disparities. In: Pescosolido B, Martin J, McLeod J, Rogers A, eds. *Handbook of the Sociology of Health, Illness, and Healing*. Handbooks of Sociology and Social Research. Springer, New York, NY.)

We follow the Institute of Medicine's (IOM) *Unequal Treatment* Report in focusing on three levels within the health care system:

1. Federal and economic health care policies and regulations at the state and federal level
2. The operation of the health care system and provider organization
3. Provider/clinician-level factors.

These domains are depicted on the left-hand side of Figure 56.7–1. The SCF extends the IOM framework by adding the parallel focus to the other key system—the community system. These additional levels are drawn from utilization, “take-up” or help-seeking models and include:

1. The environmental level, specifically social and economic forces affecting minority populations
2. The operation of the community networks, including family, friends, and the lay sector
3. Patient-level factors.

These domains are depicted on the right-hand side of Figure 56.7–1.

The touchpoint of the two systems at each contextual level produces six main mechanisms listed in the center portion of Figure 56.7–1. These include:

1. Failure of health care markets, institutional bias, limited financing, and lack of ancillary services leading to decreased access and quality of mental health care and substance abuse treatment services
2. Differential pathways into mental and substance abuse health care leading to differential experiences of treatment, no treatment, or inadequate treatment
3. Poor patient–provider interaction leading to miscommunication, clinical uncertainty, low therapeutic alliance, bias, stereotyping, and clinical errors; and high dropout rates
4. Mismatches in mental health and substance abuse service offerings and minorities’ needs leading to resistance or lack of compliance in health care and under-treatment
5. Lack of community trust and erroneous expectations of services, leading to disengagement and poor collaboration in treatment
6. Limited workforce availability and training of mental health and substance abuse service providers to treat ethnic and racial minorities, leading to reliance on informal or poorly trained providers.

In sum, at each level, the health care system and community system interact at diverse levels to produce mechanisms that lead to differential health care outcomes in mental health and substance use care, including greater illness severity and diminished quality of life. The levels and systems are linked by and through these mechanisms in a complex population health system. All mechanisms and contexts are set within a shaded region that represents culture. Below, we discuss how the interaction between systems works at each level and operates to impact mental health and substance abuse service inequities. We provide concrete examples of how the six main mechanisms may produce inequities. Because service inequities may also result from interactions between levels, some overlap is inevitable in our descriptions. Where appropriate, we bring in evidence-based concepts and findings not specific to mental health and substance abuse care to identify potential leverage points to reduce inequities that lead to these negative mental health and substance use outcomes or to create testable models tailored for diverse racial and ethnic groups. Finally, we acknowledge that the mechanisms linked to access may differ from those leading to poor quality of care or differential treatment outcomes.

HEALTH CARE SYSTEM DOMAINS

Federal, State, and Economic Policy

Federal, state, and economic policies impacting health and mental health care have the potential to create, exacerbate, or reduce health inequities. Due to their over-representation in government-sponsored programs like Medicaid, populations may face additional challenges as a result of state and federal regulations aimed toward cost control. For example, state differences in implementation of the Patient Protection and Affordable Care Act (ACA), federal financing of Medicaid payments, and the Children's Health Insurance Program (CHIP), all have a disproportionate effect on minority populations. We discuss each, in turn, below.

Affordable Care Act and Medicaid Expansion. A key provision of the ACA is the expansion of Medicaid to include adults with incomes up to 138% of the federal poverty level (FPL, $16,104 for an individual or $27,310 for a family of three in 2014), in order to increase the number of Americans who are insured. A review of 65 studies from 2014 to 2020 found that states which expanded Medicaid significantly narrowed racial and ethnic disparities in coverage among Latinx and Black individuals compared to White individuals. Few studies examined effects among other racial and ethnic groups, which is an important gap in the research. Medicaid expansion improved disparities in some indicators of access to care, quality of care, and health outcomes (e.g., infant and maternal health). Substance abuse treatment increased, with 36% more people receiving treatment after 4 years of the expansions in expansion states, compared to nonexpansion states. Despite ACA provisions, individual states are allowed to decline the Medicaid expansion, and there are still those who do not qualify for Medicaid in their state and those who earn just enough that they are ineligible for the insurance tax credits available. Since minorities tend to be overrepresented among the poor, the flexibility of states to set their own eligibility criteria has implications for minorities' access to and quality of care. An estimated 4 in 10 uninsured African Americans fall into the coverage gap. Latinxs, who have the highest percentage of uninsured when compared to other racial/ethnic groups, are also affected.

Immigrants of all backgrounds face particular challenges under current health insurance laws. Those who are lawfully present are subject to a 5-year waiting period for Medicaid and CHIP, as well as exclusions from these programs for some classes of immigration status. States may waive the waiting period for pregnant women and children, but not all states choose to do so. Undocumented immigrants are further disadvantaged, as they are not eligible for Medicaid at all, are not eligible for tax credits used to make private health insurance more affordable, and are not eligible to purchase health insurance via the federal health insurance exchange. Lack of access due to not having insurance serves as a potential mechanism promoting service inequities. Not surprisingly, it has been argued that expanding insurance coverage for minorities would partly reduce inequities.

Low Reimbursement Levels and Provider Shortages. A major challenge for Medicaid beneficiaries is having a sufficient number of providers that accept Medicaid and CHIP payments. Alexander and Schnell find that increasing payments for new patient office visits reduces reports of providers turning away beneficiaries. According to their results, closing the gap in payments between Medicaid and private insurers would reduce more than two-thirds of disparities in access among adults. The implementation of the Mental Health Parity and Addiction Equity Act (MHPAEA) was expected to reduce the large unmet need for services. According to statistics by the Medicaid and CHIP Payment and Access Commission (MACPAC), only 35.7% of psychiatrists accepted Medicaid reimbursement rates as of 2019. Low participation of physicians is particularly concerning given the expansion of Medicaid to 85.3 million people in poverty.

Low reimbursement rates, payment delays, and billing requirements have been noted as a primary reason for not taking Medicaid patients in physician surveys. Systemically, providers within organizations serving large numbers of Medicaid patients may experience high expectations for productivity in order to make services financially feasible, which can increase provider burnout. There may also be a need for providers to spend additional time coordinating care for more vulnerable patients. The implementation of Accountable Care Organizations (ACOs), which bring together groups of providers and provide more flexible payment structures to incentivize positive outcomes, may be beneficial in reducing health care inequities. Expansion of safety-net providers such as Community Health Centers (CHCs), another provision of the ACA, is another avenue by which health inequities may be reduced due to their ability to promote screening, meet cultural sensitivity requirements, provide transportation assistance, and treat all patients regardless of immigration status or ability to pay. A review of mostly quasi-experimental studies from 2000 to 2017 found that greater funding for CHCs improved access to care (including mental health care), especially among low-income and racial/ethnic minority individuals. An additional consideration is that the long-term sustainability of CHCs is partially dependent on the revenue that they can continue to generate from patients, which is more challenging in states with high proportions of uninsured patients.

Children’s Health Insurance Programs. CHIP is designed to make free or low-cost health insurance available to children without insurance but who are ineligible for Medicaid. As such, it plays a crucial role in reducing access barriers that create health service inequities among minority youth. In the first 10 years after CHIP was implemented, rates of uninsured children dropped from 30% of Latino children to 20%, 19% of Black children to 12%, and 17% of Asian, Native Hawaiian, and Pacific

Islander children to 12%. A study of CHIP implementation in New York found that preexisting racial/ethnic inequities in access, unmet needs, and usual sources of care between white, Latino, and African American youth were virtually eliminated during the first year of enrollment. However, racial and ethnic minority children continue to be less likely to be enrolled in health insurance when compared to white children, even when eligible for CHIP, and disparities are substantial among Latinx children with immigrant parents. The Current Population Survey indicates that in 2018 the uninsured rate among Latinx children with only foreign-born parents (13.1%) was over triple the rate for non-Hispanic white children (3.8%) and 2.5 times higher than the rate among Hispanic children with at least one U.S.-born parent (5.2%). It was 4.6% among Black children.

In 2009, the Children's Health Insurance Authorization Act (CHIPRA) established provisions aimed at reducing health inequities, including providing outreach grants to increase enrollment, increasing federal matching rates for interpreters and translators, providing federal funding for medical care for immigrant children in states that waive the 5-year insurance waiting period, establishing quality of care measures to track health outcomes for children, and including specific provisions addressing health concerns that disproportionately affect low-income children and children of color. Across states that enacted the additional CHIPRA coverage for immigrant children, health insurance rates for this population increased by 14.5%, and unmet health needs decreased significantly.

Mental Health and Substance Abuse Parity. Laws aimed at achieving parity between insurance benefits for general health conditions and insurance benefits for mental health conditions have been enacted in various ways since 1996. In 2008, MHPAEA was passed, and the ACA subsequently expanded the reach of the act to more types of insurance plans. The MHPAEA does not require plans to offer specific mental health benefits but rather to ensure that the benefits offered are equal to those offered for other health conditions. Implementation of the law has been a complex process, resulting in final regulations being issued in 2013. While parity provisions are a promising step forward in access to care, it remains to be seen how the enactment of current regulations may or may not impact health service inequities. Poor behavioral health outcomes persist among people from minoritized, marginalized, and oppressed populations;

thus, it is time for the model of care and advocacy in the behavioral health field to shift its priorities from parity to equity.

National Standards for Cultural and Linguistically Appropriate Services. Policies can directly address issues relevant to minorities. The National Standards for Cultural and Linguistically Appropriate Services (CLAS) were published in 2000 by the Department of Health and Human Services (DHHS) and revised in 2013. The CLAS standards provide guidelines for health care organizations addressing three areas: governance, leadership, and workforce; communication and language assistance; and engagement, continuous improvement, and accountability. These standards have been used to shape service delivery systems, as well as by some states to propose or pass legislation. Organizations are urged to provide trained interpreters, as well as linguistically and culturally adapted medical forms for non-English speakers. Among public mental health agencies in 43 states and Washington, DC surveyed in 2016, 10 had no policies corresponding to the 3 CLAS national standards, and 8 had policies in either 1 or 2 of the domains. Twenty-five agencies had policies in all 3 domains; only 8 of these had adopted all 15 CLAS standards. Improving communication within health care organizations and consistency of accountability measures may contribute to more widespread implementation. While the CLAS standards are not a federal law, failure to meet language access recommendations may be a violation of Title VI of the Civil Rights Act of 1964, which prohibits discrimination in organizations receiving federal funding. DHHS-funded organizations must provide meaningful access to services to non-English-speakers, including trained interpreters.

Policy Supporting Innovation. Policy changes can also facilitate the use of innovative strategies to address health inequities. In 2013, the Centers for Medicare and Medicaid Services adopted a regulation change allowing states to choose to reimburse for physical and mental health services provided by unlicensed providers, as long as a physician or other licensed practitioner has recommended the service. This opens a possibility for states to fill in gaps in service availability by engaging providers such as community health workers (CHWs) and other lay providers (e.g., addiction recovery coaches or peer support specialists). The use of lay providers to deliver mental health services has been successful in several major studies in underresourced communities within the United States. Further research is needed to examine the extent to which evidence-based interventions delivered by lay providers can increase equity in access *and quality* of behavioral health care.

Technology used to track the delivery of patient care and implement quality measures is another promising avenue via which to reduce health inequities. Advances in health information technology, including electronic medical records, have been a critical component of national health policies. The ACA calls for improved reporting requirements, while CHIPRA has promoted the development of standard quality measures as a way of tracking and addressing health care needs. The IOM noted in a 2009 report that more detailed information on racial, ethnic, and linguistic background collected in public health data systems would help target efforts to eliminate health service inequities. Little had changed by 2020 when many states' incomplete reporting of racial and ethnic data related to COVID-19 cases contributed to the overall delayed and inadequate response in addressing racial disparities. Combining detailed data collection with quality measures allows to identify gaps in care for specific groups and to respond with specific programmatic improvements.

In sum, the larger parameters of society shape the health care system. At the federal and state level, specific policies on health care, as well as economic policies and regulations, create a set of market forces. In turn, the nature of these health care system policies interacts with the contours of the community system to impact the experiences of ethnic and racial minorities. We describe both the intended and unintended consequences of these policies on health care organizations next.

Operation of the Health Care System and Provider Organization

As a result of the system-level factors described above, health care systems face differential costs and opportunities associated with treating ethnic and racial minority populations. As noted above, reimbursement by the state or the federal government holds a central role in shaping provider burden, service design, workforce diversity, and the organizational climate of health care organizations.

Cultural and Linguistic Competency in the Operation of the Health Care System. Health care policies designed to encourage cultural and linguistic competence, such as the CLAS guidelines, are expressly designed to counter discrimination. Yet, the ways in which a policy is implemented by organizations and providers impact client care. Language barriers for non-English speaking immigrant groups create major challenges in access to care. In one study alone, language barriers between provider and patient accounted for a $38 increase in charges for testing and increased length of stay in the emergency department. Patients who speak a different language from their providers report worse outcomes and higher dropout rates and may experience misdiagnosis or poor treatment based on misunderstandings in assessment. The use of interpreter services by competent providers has been shown in some instances to result in lower-quality care when the interpreter is not knowledgeable about mental health conditions or tries to make their own interpretations. However, a study of 452 Spanish-speaking patients seen for behavioral health visits in primary care found that interpreter use did not impact therapeutic alliance when compared to working with bilingual providers. Qualitative data from a subset of patients indicated a preference for working with bilingual providers when available, but found patients were satisfied with behavioral health care services delivered via interpreters and saw them as a way to increase access to care.

At the same time, improving linguistic competence within a system results in additional costs and time investment. Health systems may be reluctant or simply unable to cover these resources. Furthermore, even if willing, individuals may not be readily available or trained to fulfill the required services. Medical interpreters may not receive specific training in mental health care interpretation. Policy efforts such as state legislation based on the CLAS standards may be beneficial in reducing health inequities, but resources and training must be available to health care systems to finance and implement organizational change. A review of health care organizations' implementation of the CLAS standards suggested that barriers to CLAS implementation include a lack of awareness of the benefits of CLAS, perceived complexity of implementation, and organizational resistance to change. Recommendations identified across studies included providing sufficient language access services (i.e., professional interpretation and translation); ensuring data collection on race, ethnicity, and language as related to patient services; and obtaining buy-in from leaders and administrators. Community engagement, workforce development and training, and strategic implementation across all organizational levels were also highlighted.

Integrated Health Care. The integration of behavioral health services into the primary care setting has been advanced as a strategy to improve behavioral health outcomes for minority populations, given studies that indicate that members of racial and ethnic minority groups are more likely to seek mental health care via their primary care providers (PCPs). Yet, only limited data are currently available on how to best implement high-quality behavioral health services for minority populations in primary care. Studies have found that PCPs are less likely to detect mental health concerns among racial and ethnic minority patients compared to white patients. The pressure to treat behavioral health challenges in the time-limited setting of primary care, in addition to constraints in specialty care options available for PCP referral, may result in situations in which clients are offered lower-quality services or do not follow up on treatment. One study found that Latino primary care patients diagnosed with depression were more likely to follow up on and complete treatment via medication alone, despite the majority of the patients expressing a preference for psychotherapy over medication. These patients were able to access medication directly via their PCP but may have experienced challenges in accessing therapy services.

Research on models of integrated and collaborative care, as well as their impact on specific racial and ethnic minority populations, is needed in order to explore how this approach may or may not reduce health service inequities. As one of the most studied models of integrated care, collaborative care shows promise as a strategy to reduce inequities. A review of studies of collaborative care for depression among limited English proficiency patients (LEP) concluded that collaborative care delivered by bilingual providers was more effective than usual care. Weaknesses in the evidence base included a low number of studies (particularly for languages other than Spanish), lack of information about whether cultural adaptations were made in addition to language adaptations, and lack of research examining why LEP patients are less likely than English-proficient patients to be enrolled in collaborative care programs. A review of collaborative care for racial/ethnic minority patients similarly found it to be a promising approach to improve depression outcomes but found that studies encountered challenges in recruitment of racial/ethnic minority patients.

In other ways, the design of health care systems and services contributes to inequities. When health care organizations do not offer effective treatment for behavioral health problems, issues such as alcoholism, substance dependency, or posttraumatic stress disorder affect health status directly and compound other health problems indirectly. Further, offering a service-level spectrum, whereby good quality health services are offered for services that attract the healthy, but poor-quality services are offered for the sick or those with chronic conditions (referred to as “adverse selection”), tends to discourage use and hinders good outcomes.

Organizational Climate and Institutional Racism. Outcomes research has demonstrated that the climate of attitudes and beliefs and culture (both normative expectations and actual behaviors) in the provider organization toward minoritized populations affects the receipt of quality care. For example, epidemiologic evidence indicates that racial and ethnic minority patients have lower rates of mental health disorders overall but higher levels of severe illness and a lower likelihood of receiving mental health care, reflecting structural inequity. As a result, racial and ethnic minority patients may come to mental health and substance abuse care at higher levels of illness severity and terminate treatment early. This may reinforce a cycle of bias and discrimination, in which providers view patients as requiring more resources and intensive treatment or are seen as typically less adherent. In addition, these patients may also require referrals and networking with other social and service agencies—work for which the health care provider is not compensated. Rather than recognizing structural racism as a root cause of these inequities, providers may maintain negative attitudes towards patients or ascribe cultural explanations to structural conditions. Structural competency has been advanced as a paradigm shift in medical education and practice, away from a focus on stigma and cultural competency towards a focus on recognizing how structures, including social and economic forces, shape clinical interactions and how these conditions in turn call for structural interventions. At the organizational level, the use of evidence-based strategies for organizational change, such as the ARC (Availability, Responsiveness, Continuity) intervention model, may be an avenue by which to change organizational attitudes. In this model, “change agents” are trained to educate providers, advocate for systems-level change, provide implementation data and feedback, and facilitate communication within the organization and with the broader community.

Design of Services for Minority Groups. While the evidence is inconclusive on whether the lack of targeted services for diverse patient populations plays a central role in service inequities, a meta-analysis showed that culturally appropriate interventions were four times more effective than those not targeted to specific cultural groups. Further, interventions conducted in the client's native language were twice as effective as those conducted in English. Yet, there is a serious shortage of culturally appropriate behavioral health services for ethnic minority youths. In a review of psychosocial interventions, Pina and colleagues found that there were no well-established interventions effective for treating trauma or stress reactions, self-injurious behavior and suicidality, or comorbid disorders or multidisorders among ethnic minority youth. There is also a need to address the disproportionately high rates of suicidal behavior and homelessness among BIPOC youth who are LGBTQ. Policies cocreated in partnership with these youth are likely to be more effective in meeting their needs.

Structuring for racial and ethnic concordance or matching between patient and provider is one area of heated debate. Race concordance for African Americans has been associated with higher patient participation in decision-making and greater satisfaction with care. Patient–provider matching also tends to improve retention of clients and intervention outcomes and may increase entry and adherence to treatment. If this is, indeed, the case, professional services in culture-specific clinics might be a tool for providing better services to ethnic minorities. However, there is limited evidence on whether or not they reduce service inequities. While ethnic similarity may facilitate retention in therapy, it may have only a minor role in therapy outcomes. Similarly, physician's race concordance with patients does not appear to be associated with either the use or quality of care, only with preventive care.

Clients are likely to respond to the therapy in ways that are consistent with their cultural socialization regarding care. Therefore, culture most likely defines the options perceived to be available, useful, and/or desirable behaviors of what is culturally expected of the therapist and client roles. Patient preference for one theoretical orientation over another might characterize members of cultural groups. Researchers hypothesize that therapists and clients who are ethnically similar may be more analogous in terms of problem perception and attitudes about coping and treatment goals, and some studies have found that patients delay treatment based on the perception that an ethnically dissimilar clinician will not understand their needs. As a result, these coinciding factors may improve the effectiveness of therapist/client interactions.

This is not to say that all racially/ethnically concordant patients and providers will share the same attitudes and beliefs. Research has demonstrated that *cognitive* match between patient and provider is most important, with evidence of this significance persistent even after controlling for ethnic match and the client's language preference. These findings have implications for practice/training and for the need to assess discrepant orientation and treatment ideas. Across studies, reasons for patients not initiating treatment included interpreting that the mental health system could not help them, the belief that somatic symptoms were not related to mental health conditions, and stigma (though interpretations of stigma varied). Reasons for not continuing treatment included feeling discomfort discussing emotions with strangers, preferring a particular clinician communication style, and having concerns about clinician power and authority.

Provider-Level Factors

Use of Guideline Concordant or Evidence-Based Treatment. Providers' reluctance to adopt evidence-based treatments (EBT) when serving minorities has been well-documented, leading to service inequities. The question remains as to whether the deviation from EBT is greater among providers who serve primarily ethnic and racial minorities or whether providers are less likely to provide EBT to their minority clients. Evidence has been found for both; clients who are poor or African American and Latinxs have been found to be less likely to be offered the more rigorous or intensive care options provided to those who were more advantaged, but also facilities serving mostly ethnic and racial minority patients were less likely to offer evidence-based care. For example, a study of services received by low-income adult patients with anxiety disorders in a community mental health center found that the majority of patients received pharmacotherapy, and that of the minority receiving psychosocial treatment, they were receiving supportive therapy rather than the established evidence-based practice of cognitive-behavioral therapy (CBT). Only 3.8% of patients with an anxiety disorder received the most effective treatment, exposure-based CBT. However, many health care institutions do not provide sufficient support for providers to adopt quality behavioral health care within the pressures for productivity.

Research examining the use of medical procedures across chronic illnesses, such as depression, has consistently found a lack of referral of minorities for EBTs when compared with non-Latino whites, even when minorities meet clinical appropriateness criteria for EBTs and when age, gender, and insurance status are controlled. Although longitudinal studies examining changes in trends for inequities in EBT among Medicare-managed care patients indicate that racial inequities in EBT have declined for some illnesses, for mental health care, the gap in EBT for minority patients remains.

Provider's Attitudes and Perceptions: Uncertainty, Stereotyping, and Bias. Providers seldom receive training issues surrounding stigma, either in the community system or in the health care system. As a result, there is reason to assume that they carry the prejudices of the communities they live in and the health care systems in which they work. Stigma attributes causes of behavior (genetics, socialization, character), assign characteristics to individuals (e.g., violent, unintelligent), and ascribes beliefs about health behaviors (noncompliant) that are embedded in individuals, organizations, and places. Stigma interferes with how the problems of ethnic and minority group members are conceptualized, how treatments are planned, and what expectations are held for recovery. From the start, providers do not have the cultural tools to motivate minority patients to voice their symptoms, treatment concerns, or preferences. Providers display fewer patient-centered behaviors, are less receptive to question asking, and tend to demonstrate greater verbal dominance with minorities than with white patients. This can lead to miscommunication and misunderstanding between the patient and provider, resulting from cultural or language differences. In turn, this contributes to uncertainty in the clinical encounter, which is well documented to increase provider hesitancy in treatment which may manifest in disparities in clinical decision-making, treatment planning, care provided, and outcomes. When cultural differences have diagnostic implications for clinical symptoms or for signs or tests due to atypical symptom presentation, providers have incomplete information about the efficacy of a therapeutic intervention. This is not surprising because research on these deep cultural differences is not supported or regarded as highly as standard treatment-based research, and, even in the latter, minorities are under-represented in clinical trials.

Stereotyping of minoritized patients by health care professionals, documented in a number of recent studies, is another potential source of service disparities. Even if stereotyping stems from unconscious bias, reflecting limitations in cognitive mechanisms, the effects on inequities are real, nonetheless. Categorizations such as race, age, sex, and socioeconomic status are overgeneralizations and produce statistical discrimination, which goes directly against the more tailored precision approaches. For example, providers tend to see Black patients as less educated than non-Latino white patients. Providers' implicit bias has consistently been linked to worse perceptions of interactions with health care providers among African American patients. Finally, provider-based biases have also been posited as negatively influencing clinical decision-making.

Both over and underdiagnosis could result from these stereotypes and negative biases. Overdiagnosis occurs when appropriate behaviors in one culture are interpreted as pathologic by a professional from another culture. Incorrectly diagnosing a psychotic disorder where none exists could result in inappropriate hospitalization or in the use of potentially dangerous antipsychotic medication. For example, in more extreme cases, certain cultural or religious beliefs and practices common among Latinxs and African Americans accept, and sometimes encourage, visual and hearing perceptions of supernatural experiences, which are interpreted by professionals in the dominant culture as pathologic hallucinations. In an epidemiologic study in Puerto Rico, 13% of the population reported some kind of hallucination. Yet, a qualitative analysis of these symptoms by trained local psychiatrists revealed that they occurred mostly in the context of religious or spiritualist experiences and were not pathologic. Not surprisingly, recent epidemiologic and clinical research has raised questions about the relationship between the endorsement of psychotic symptoms and the diagnosis of psychotic disorders among culturally diverse groups.

Underdiagnosis occurs when clinicians ignore genuine manifestations of mental illness, misguided by a misinterpretation of cultural sensitivity. The absence of cultural and contextual information contributes to an elevated probability of misdiagnoses and inappropriate treatment formulation. A growing body of research has documented that minority patients were more likely to report that their provider did not discuss end-of-life care and were less likely to receive recommendations for how to quit smoking or engage in diet and exercise. Providers may unintentionally or intentionally dismiss minority patients’ concerns or may not communicate about health promotion, psychoeducation, or early screening for mental disorders. Only one-quarter of Latinxs surveyed in the National Latino and Asian American Study reported ever being asked about alcohol or drugs. Fewer than 20% of Latino patients reported ever being asked about emotions, nerves, or mental health problems. This limited inquiry may lead to missed opportunities for early identification of mental health or substance use disorders and a lack of referral to specialty services.

Clinician Training in Cultural Responsiveness. The concern with provider-based bias does not translate into the notion that there are no beliefs in ethnic and racial communities that interfere with treatment. In a recent study on COVID-19 vaccination intentions, the fact that individuals from diverse racial and ethnic groups worked in a health care setting did not offset disparities. Asian, Black, and Latinx individuals, as well as those who identified as multiracial, expressed a lower likelihood of vaccine uptake. This provides a clear caution about assuming the health stance of individuals based on relevant sociodemographic categories. While cultural responsiveness training has been offered as a solution to the problems described above, it is not yet an integral part of the education of many health professionals. Health care personnel typically have limited training in the cross-cultural formulation and cultural humility, leading to a lack of concordance in defining the problem and treatment goals. There is also evidence that providers signal their expectations about patients’ outcomes and whether they believe there will be improvements, which may be related to actual patient health outcomes. For example, health care professionals may communicate lower expectations of treatment outcomes for socially and economically disadvantaged patients, which could discourage minority patients and lead to poor outcomes and low treatment retention. Furthermore, clinicians and researchers have called for a move beyond cultural competency to structural competency, calling for increased focus in medical education and health care practice on understanding how social, economic, and political forces, including structural racism, produce downstream health care conditions.

THE COMMUNITY SYSTEM

Community systems differ dramatically in a series of characteristics that both can facilitate the use of services and offer protection against health problems. In the SCF, the community is defined as “a group of people with a similar cultural origin and diverse characteristics that are linked by social ties, share common perspectives, and engage in joint action in geographical locations or settings.”

Environmental Level

Neighborhood context influences both individual health and health behaviors. Residing in socioeconomically disadvantaged neighborhoods has been linked to poor health outcomes due to built-in environment factors (e.g., increased exposure to pollutants and decreased access to green spaces); limited access to health care facilities and health care providers; poor quality of available health care; stress related to poverty and neighborhood violence; limited opportunity for economic mobility; disproportionate contact with the criminal legal system; and decreased social connectedness. These circumstances are not accidental. Political policies, such as redlining predominantly Black neighborhoods, decreased residents’ access to secure mortgages and opened up their neighborhoods to natural risks (e.g., flooding).

The geographical area in which minority populations live helps to create a social context which, in itself, fosters a lack of connection with treatment systems and the dominant culture. Geographical segregation continues, perhaps even at greater levels than would be expected for minority populations. In a nationwide study of data from over 25 years, Chetty et al. found the black–white gap in income mobility persists even among boys who grew up in the same neighborhood. Fewer than 5% of Black children grow up in low-poverty neighborhoods, which also have low levels of racial bias among whites and high rates of father presence. Members of immigrant groups have a variety of experiences with resettlement depending on the time period in which they arrived in the United States, the circumstances of entry, and the political and social climate towards the particular group at the time. Thus, the social context and the geographical context are often intertwined and overlapping. This impacts health on multiple levels, from the prevalence of particular conditions to access to and use of mental health and substance abuse services.

Level of Social Cohesion

Community social cohesion may play a role in health inequities by influencing factors that affect service outcomes. For example, there is evidence that organized and cohesive communities are able to ensure that state budget cuts do not affect their community and this, in turn, allows them to maintain increased access to funding for health and education. Neighborhood social cohesion has also been associated with greater use of preventive health care services. Beyond service use, social cohesion may impact health outcomes more directly as well—it has been shown to moderate the impact of neighborhood built environment (e.g., structural disadvantage, urban green space) on mental health.

Social Capital and Social Networks

While it is difficult to draw a clear line between the “community” as “place” and the “community” as “people,” the difference is important. While a place can shape the personal connections that individuals have, social scientists also focus on the community as individuals’ “small worlds”—that is, the actual nature of social ties and social interactions that individuals have in a geographic area. Family, friends, and even casual contacts can recognize a problem, may facilitate or inhibit help-seeking, and may influence adherence in future medical contacts, filling prescriptions, and adhering to lifestyle advice. Community ties shape how people recognize, interpret, and guide an individual’s reaction to the onset of mental health and substance abuse problems. They also continue to exert influence throughout the entire illness career. That is, not only do social networks constitute individuals’ “community of meaning,” but they are also their “community of influence.” Research has found social networks to play a key role in whether individuals deal with mental health and substance use problems or dismiss them, whether they rely on the family alone or seek professional help, and whether they are welcomed back into the community or rejected. All considered, social networks are critical in the course and outcome, especially in recovery from substance use disorders. For individuals from cultures that are wary of the formal treatment system and who are immersed in a strong family system, this can result in delays in care and/or the burnout of their social networks. However, when the health care system has a known concern for and tradition of understanding the population groups under their purview, social networks can facilitate care, communication, and recovery.

Service systems working with minoritized families need to consider the important role of extended family and “fictive kin,” that is, individuals who are not related by marriage, birth, or adoption but who are also possible sources of support or burden in treatment. For example, in strong and tightly meshed family networks, such as those of most Latinxs, African Americans, and Asians, individuals may initially be discouraged from seeking professional health services, feeling that the family should handle the situation. Only when family support systems are lacking, or become ineffectual in handling a crisis, do some culturally diverse families turn to professional help, even then activating social networks contacts to find trusted sources of care. Yet family support and supportive social networks have also been commonly shown to *facilitate* service use among African American adolescents, particularly when caregivers have had positive experiences with mental health services and/or refer their children.

Access to mental health services is a *process* that is relational and socially embedded. One way that nonprofessional support can lead to formal support is through group social identification. Self-identifying as a person with a mental illness or addiction and identifying with other people who have the same condition can promote professional help-seeking, in part by reducing stigma. Innovative strategies that leverage the influence of community networks can facilitate health and health care. Certainly, the role of churches and community centers in African American neighborhoods has been leveraged as a way to reduce vaccine hesitancy during the COVID-19 pandemic, as was the case for HIV education and testing. Trusted community organizations offer a way to embed health care services in the settings in which individuals and families naturally seek help.

Individual Factors Other than Need or Clinical Appropriateness

General Education. The number of years of schooling is directly linked to the development of effective capabilities that influence subsequent life conditions that have an effect on health, including economic welfare, healthy lifestyles, and full-time employment. Higher rates of education have been shown to positively impact mental health by increasing one’s resources to cope with adversity or increasing a sense of control over one's destiny. Low educational attainment is not only a strong predictor of poor mental health and substance abuse outcomes for children but remains significant for mid-age and older cohorts.

Health Literacy and Numeracy. Health literacy has two components—knowledge of health issues and knowledge of what to do if a health problem arises. The first is a skill involving both oral and written communication that may or may not be related to educational attainment. It is a twofold concept that includes the individuals' basic literacy skills and the application of those skills within the health care system. A related concept, health numeracy, involves not only understanding mathematics but also quantitative concepts such as "reduce/increase." The IOM has highlighted that health literacy is not solely an individual skill; rather, it results from the interaction between individual capacity and the demands of the health care system. It can also result from what "others" around individuals know. Inequality in educational opportunities and resources also contributes to why public health researchers conceptualize health literacy as a "midstream" determinant of health.

Health literacy may indirectly create barriers to health care use by inhibiting access to care due to a patient's inability to register for health insurance; difficulty in interpreting coverage benefits and rules; avoidance or delays in accessing health services due to the inability to adequately fill out forms in physician offices or difficulty following directions to service facilities. Once individuals with poor health literacy enter care, they face inequities in health outcomes associated with literacy limitations, with people who read at lower levels being 1.3 to 3 times more likely to experience adverse health outcomes than individuals with high literacy levels. They are also more likely to report poor health, have an increased risk of hospital admission, and have incomplete understanding of their health problems and treatment.

On the second dimension of health literacy, awareness of relevant resources, inequities in health care among some racial and ethnic minority children appear to be linked to parental knowledge of the disorders and available treatments. Zuckerman and colleagues have found that compared with non-Latino white parents, parents who were Latino or other ethnicities had less familiarity or personal experience with developmental disabilities, like Attention Deficit and Hyperactivity Disorder (ADHD) and Autism Spectrum disorder (ASD). One study suggests that parents' level of English proficiency and parents' knowledge about ASD are related to disparities in Latinx children's ASD diagnosis and treatment in the United States. There is also evidence that different ethnic groups in the United States have varied perceptions of what is considered a mental health problem in their offspring. In one study, Latino and African American parents rated their adolescents' mental health and life satisfaction as better than their non-Latino white counterparts and overall perceived fewer emotional or behavioral problems in their children. These differences existed even after adjusting for the clinical needs of the child, the child's level of impairment, and the sociodemographic characteristics of the parents. Thus, while a lack of knowledge about a problem may lead to health inequities, it is also possible that different perspectives on a situation may lead to different patterns of seeking care.

Negative Provider Stereotypes. Patient views of providers may prove to be influential factors in causing inequities for racial and ethnic minority populations. For example, research revealed that individuals holding strong negative stereotypes of physicians are more likely to delay care or only seek treatment once symptoms become severe or impede daily functioning. Therefore, if delays in treatment are due in part to negative stereotypes, service inequities in illness prevention or early intervention may emerge. Negative stereotypes of physicians may result from patients' own history of negative treatment in care or the distrust many minorities feel towards the health care system. However, recent population-level research in the United States has documented very high endorsement of general and specialty providers for unlabeled situations that meet DSM criteria for psychiatric diagnoses of schizophrenia or depression. While there were few, if any, differences between majority and minority group populations, the response to individuals with alcohol dependence revealed continued and even increasing stigma.

Patient's Competing Needs. Some ethnic and racial minority patients may come from low-income backgrounds with complex social needs. Lack of access to paid sick leave, inflexible work scheduling, irregular hours, lack of transportation or unreliable transportation, and difficulty obtaining childcare all pose additional challenges to utilizing health care services. Studies have found that these barriers account for both missed appointments and lack of follow-through on specialty referrals.

WHEN HEALTH CARE SYSTEMS AND COMMUNITY SYSTEMS MEET: MECHANISMS PRODUCING INEQUITIES

Taken together, inequities arise when disadvantages in the health care system interact with those in the community. At each level, the SCF suggests that six fundamental mechanisms produce inequities for minoritized populations. These are represented as the center stream in Figure 56.7–1. While they link with causes of inequities, they also suggest points of intervention. They represent potential leverage points for systems, providers, and patients to change the health care system, existing policies, clinical training, and community programs. Below, each interface between community and treatment systems is explored.

1. Failure of health care markets, institutional bias, and limited financing leading to decreased access to and utilization of mental health and substance use services. State and federal regulations aimed toward cost control also contributed to the increase in the number of uninsured or underinsured. For example, individuals are typically excluded from Medicaid as states respond to increased costs by enacting more stringent eligibility criteria. Yet, the expansion of public insurance programs and subsidized private plans to low- and middle-income individuals offered under the ACA can increase access to care. Nonetheless, some minority groups may confront other hurdles to getting insurance, such as lack of citizenship or documentation status, or may still have difficulty paying for subsidized coverage, leading to a lack of insurance or underinsurance. While health insurance coverage facilitates access, it is not a sufficient condition for ensuring behavioral health care since lack of available appointments is a serious barrier to mental health and substance use treatment. The low number of mental health and substance use providers accepting Medicare and Medicaid reduces access to quality care for low-income and vulnerable populations. However, other factors such as increased HMO penetration, augmented provider supply, and the presence of a community mental health center in neighborhoods of color have been shown to reduce service inequities.
2. Differential pathways into services leading to differential experiences of service, delayed utilization, no service, or inadequate service. Language barriers can lead patients to drop out of care, opt for

alternative services, or delay care. Inaccuracies in assessment can also result in mistreatment or misdiagnosis of minority patients. There is mounting evidence that minority patients receive lower quality treatment and receive treatment for a shorter period of time. For example, white youth are more likely than minority patients to receive adequate care following a major depressive episode, while minority youth are less likely to be prescribed psychotropic medications, even after adjusting for need factors. Equally importantly, the larger cultural context determines how similar social networks can facilitate or delay treatment. Competing demands on time from work and childcare for minority parents may constrain minority families from engaging in treatment, given more urgent matters.

Thus, differential pathways into services may represent a key mechanism leading to service inequities among racial/ethnic minorities, with lack of patient problem recognition, differential referral and treatment by providers, and barriers to care serving as potential precipitating factors to inequities. Noting the insufficient attention to dynamics of pathways to treatment, Alang and McAlpine found that individuals who were “ordered” into care (i.e., followed a coercive or heavily recommended pathway) either for a mental illness or substance use disorder were less likely to rate treatment as effective compared to those who made an independent decision. Not surprisingly, they also found that individuals who are ordered into care are more likely to be African American (86% more likely) or Latinx (twice as likely), with the former significantly less likely to report effectiveness. They conclude that pathways to care reflect differential positions in the social hierarchy.

Other pathways result in inequities that may have both short- and long-term effects. For example, Latino and African American children are overrepresented in the juvenile social service sectors. They receive fewer therapeutic services compared to clinically comparable white children and remain longer in services. As a result, data analytics are being used to detect patients at risk of receiving lower-quality care based on demographic and illness-related factors, and payment systems used to incentivize providers for providing high-quality care to these patients. Nonetheless, there is considerable debate over the utility of pay-for-performance measures in achieving specific goals at the level of hospitals and the health system as a whole. ACOs may help eliminate inequities by rewarding health care systems for efficient use of resources and positive outcomes and penalizing them for inefficiency and poor results.

3. Poor patient–provider interaction leading to miscommunication, clinical uncertainty, low therapeutic alliance, stereotyping and clinical errors. Patient–provider match and expectations for a visit are important in determining treatment outcomes. However, attempts to address research documenting problems arising from poor patient–provider interaction have inadvertently produced additional problems. Ethnocentric models of health service delivery may overpathologize minority behaviors that differ from those of the majority culture. Racial and ethnic minority patients report being treated with disrespect or being looked down upon more often than non-Latino white patients. The critical link to inequities lies not only with what happens in the clinical encounter but with the resulting effects on the patient's utilization of health care and on the advice they offer to others in their lay network. For example, patients who reported being treated with disrespect were less likely to go for a routine physical exam within the last year, to have received optimal care for a chronic condition, and to have followed their doctor's advice.

   Patients may also have different expectations of treatment and provider behavior that impede effective communication. A number of studies have reported that differences in race and ethnicity between patients and their providers can present barriers to effective communication and partnerships for care. Inequities resulting from barriers to effective communication between racially/ethnically mismatched patients and providers include: discordance in the understanding that patients and providers have regarding disease causation and effectiveness of treatments, significantly lower reports of physician participatory decision-making styles by minority patients as compared to nonminority patients, and lower rates of receiving preventative and necessary medical care among Black patients with non-Black physicians compared to Black patients with Black physicians. These examples demonstrate that patient–provider match and expectations for a visit are important in determining treatment outcomes.

4. Mismatches in mental health and substance use service offerings and minorities' services needs and living circumstances leading to dropout and low or no service use. Services inequities have been linked to higher disability and greater disease burden in minority populations.

One of the mechanisms by which service inequities take place is through the mismatch of services to the patient’s needs. As we described earlier, there is substantial evidence of the potential for clinicians to engage in “statistical discrimination”—that is, to incorrectly assign a classification or social categorization to a patient that aligns with negative stereotypes, particularly when the patient’s request or symptoms are ambiguous. Under such conditions, clinicians may inadvertently incorporate attitudes and beliefs from prior clinical encounters or common stereotypes. This may lead clinicians to disregard individual data and consequently mismatch services to needs. This mismatch of services to needs can result in decreased utilization of and access to health services and health resources as well as differential outcomes in health and greater disease burden. In the absence of cultural and contextual information that supplants stereotypes, there is an elevated probability of misdiagnoses and inappropriate treatment formulation. Minoritized populations are more likely to have nonconcordant psychiatric diagnoses in psychiatric emergency services and to be undetected for mental health disorders in primary care. Research reveals that symptom presentation varies across racial and ethnic groups and can differ from what most clinicians are trained to expect. Not surprisingly, racial and ethnic minority patients are less likely to be offered “talk therapies” such as counseling and tend to be prescribed higher drug dosages than their white counterparts.

Dissimilarities in the typical conditions in which many minority populations live as contrasted to their providers (i.e., including poverty, lack of economic opportunity, food insufficiency, inadequate housing, social exclusion, low access to educational opportunities, and unsafe neighborhoods) can lead to social inequality that needs to be tackled by the health care system. As such, there has been a call for health equity research that prioritizes multilevel interventions, addressing structural and contextual factors at the community, organizational, and individual levels. Multilevel interventions to amplify social connection in minority neighborhoods could increase behaviors that have a positive or protective effect on health, such as exercise, expansion of social networks, and better problem-solving.

5. Lack of community trust and erroneous expectations of services leading to disengagement and poor collaboration in health care service systems. Local perceptions of health services affect utilization and

depend on prior experience with the provision of services and the efforts that the local service system has made to understand and adapt to the cultural and need demands of its clientele. Studies, including a qualitative analysis of an Afro-Caribbean community, revealed that their experience of mistreatment and social exclusion by health professionals reverberated on future utilization and on community sentiments toward the mental health system. In addition, African American families report fearing that their children would be institutionalized and express this fear as an important reason for not taking their children to treatment. Repeated negative contacts with the health system or with a lack of trust in key gateway providers such as teachers result in community-held beliefs that decrease help-seeking and produce health service inequities for minoritized populations.

6. Limited workforce availability and training of service providers to treat ethnic and racial minority youth leading to reliance on informal or poorly trained providers. The disproportionately low geographic supply of providers, particularly multilingual service providers, in communities with ethnic and racial minorities as compared to nonminority communities translates into market failure to provide more and better-quality care to minorities. For example, communities of color have been found to be four times more likely to have a shortage of providers, regardless of community income. Low reimbursement rates from public and private payers can lead to a shortage of services and provider burnout. Health care organization arrangements for distributing providers to minority Medicaid beneficiaries have also been suggested to be influential in-service inequities. Only 7.8% of psychologists, 12.9% of social workers, and 21.4% of psychiatrists are from racial/ethnic minority groups. Medicaid beneficiaries, particularly those with limited English language skills, may not be able to access physicians with a high caseload of privately insured patients.

Communities with high proportions of black and Latino residents were four times as likely as communities with non-Latino whites to have a shortage of physicians regardless of community income. In parallel, health care services available through the Indian Health Services vary widely across tribes. The Indian Health Services partially offsets the lack of insurance for some uninsured American Indian and Alaska Natives (AIANs), but important needs are left unmet. This is problematic since AIANs were more than two times as likely to be uninsured than non-Latino whites. These findings have led to the conclusion that the elimination of racial/ethnic health inequities is an issue of distributive justice which entails redistributing valuable material resources and opportunities to those in the lower echelons of society.

In sum, the interaction of the health care system and the community system at different levels produces a mismatch in cultures—not only the culture of medicine and the culture of everyday life but in the mismatch of dominant cultural ideas and those that may be unique to minoritized populations. Oftentimes, the beliefs of both patients and providers are based on generalized cultural beliefs and do not cut through those prejudices to get to individualized care. Equally important, both actual experiences and a family's, provider's, or community's experiences can produce a view of treatment that limits the receipt of effective care.

FUTURE DIRECTIONS: RESEARCH AND INTERVENTION

The SCF is intended to help conceptualize and carry out research directed at eliminating ethnic and racial inequities, to assist in the training of health and social agency personnel, and to supply service planners and policymakers working hypotheses, initially, and a science-base, eventually, on how to intervene and eliminate service inequities. As evidenced from our review of extant theory and research, traditional service models should be restructured in order to reduce service inequities for racial and ethnic minority populations.

However, it is important to understand the role of a framework and the difference between a framework and a model. As Nobel Laureate Elinor Ostrom pointed out, theory provides an understanding of a complex whole. A framework brings together extant findings from different branches of science to provide a picture of how the entire system operates and what are the key subsystems and factors at work in each subsystem. Doing so is complicated because different disciplines have their own very different frameworks, theories, and models that they employ to understand their parts of the complex system. But without an organizing whole, findings are not likely to cumulate, discrepant findings are not explicable, and unintended consequences in translation to policy and programs are more likely.

The framework, as an organizing picture, must be translated into a testable model for the particular problem at hand and the research question to be answered. The framework offers an overview of potentially relevant variables to be considered, orients researchers to issues in research design, data collection instruments and approaches, fieldwork protocol, and even potential analytic strategies. For example, a complex population systems framework aligns with the current discussion of the utility of multilevel modeling. This is a relatively new tool that now allows the consideration of different contexts in the same analyses. This is important because when there are nested levels (e.g., samples of individuals who live in different cities), these specialized analytic approaches, for example, correct for the violation of independence of cases assumed in regression analyses. Without these corrections, the determination of statistical significance is off. However, the data requirements to be able to analyze the effects of different contexts are very high, requiring a large number of contexts (e.g., neighborhoods, counties) at the higher level. It would be impossible, or nearly so, to develop a feasible research study that could incorporate everything in a framework.

That said, from the SCF, we posit six mechanisms that form a foundation for rethinking intervention strategies: (1) increased client/patient activation/empowerment; (2) information exchange between client and provider; between systems and communities addressing social networks rather than individuals alone; (3) new and/or different policies to increase access to services and quality of services; (4) better treatment matching; (5) restructuring of service systems to reduce reliance and action based on stereotypes, prejudice, and clinical uncertainty; and (6) quality collection of data on racial and ethnic disparities to improve system accountability.

1. **Patient activation.** Patient activation, defined as learning the knowledge, skills, attitudes, and self-awareness necessary to have greater decision-making and efficacy in health care behavior, has been associated with improved health behaviors such as exercise, disease self-management behaviors such as adherence to drug regimens, and an array of health outcomes including improved mental health. There is evidence that patient activation enables patients to take more charge of their health behavior, elicit more information from their provider, achieve greater satisfaction in the clinical encounter and better outcomes and increase engagement and retention in care.

2. **Information exchange.** Information exchange is based on a dialogue between patient and provider or between community and health service system so that the provider learns about the social context (i.e., where patients live, what they do, what matters to them, their social position, and their environment and cultural perspective of the patient). There is evidence that information exchange promotes a more egalitarian view of the information needed for a patient-centered encounter and to structure treatment recommendations or proposed behavioral changes acceptable in the patient's daily lives. If service use and provider action depend on a social influence process in the community as well as individual predispositions as has been documented since the 1970s, then understanding and using effective diffusion methods are likely to be more effective and efficient.

   However, information has a larger system component as well. Further, a recent *JAMA* editorial laid out the role of technology, especially the digital divide, in the differential rate of vaccination between minority and majority populations and among age groups. They noted that while there have been important recommendations offered to promote equity in the distribution of COVID-19 vaccines, they have missed the information component, which requires not only information and skills to sign up and do so quickly, but a recognition of the gaps in home-based broadband (40% among older people) and the greater likelihood of dead zones in minority communities. Yet, national guidelines and expert recommendations have neither considered nor proposed solutions to technology-related equity challenges.
3. **Policies.** Policies include decisions by organizations such as routinely providing assistance to patients in communicating with their providers or regulations by governments or public authorities such as deciding eligibility criteria for Medicaid services. Recent research has demonstrated the larger health effects of policy changes that are critical for disadvantaged populations. When the U.S. Department of Agriculture mandated that the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) move from a paper voucher to an electronic benefits transfer (EBT) debit card, participation in this program increased substantially (7/8%). This was, even more, the case in states that heretofore had the lowest WIC participation rates. This has direct implications for health. Research has clearly documented that WIC improves health outcomes for pregnant women,

infants, and young children. An example of a policy change could be a new requirement that interpreter services be readily available in the clinical encounter if English is not the primary language of the patient. Another policy to increase equity could be mapping areas where few mental health providers accept public insurance programs to provide additional incentives (i.e., higher reimbursement rates) for providers to offer care in those areas.

4. **Better treatment matching.** Better treatment matching includes the provision of linguistically appropriate services as well as treatment and outreach options that are socioculturally compatible with the circumstances of the target population. There are three basic criteria on which to judge whether there is treatment matching of services: the treatment/services are based on the cultural values of the groups of interest; the strategies involved in the treatment/services are congruent with the culture and context of the particular ethnic/racial group, and the components of the service/treatment strategy are based on the expectations and behavioral preferences of the ethnic/racial groups. It is argued that the treatment matching of the services/treatments with the patient/community is necessary for quality improvements to be institutionalized and sustained by the service organization and acceptable to the community.
5. **Restructuring of services.** Restructuring of services involves an organizational change to better accommodate the needs of clients. Settings that are accessible to communities and which they trust (i.e., community-based organizations, churches) might be more acceptable as settings for health or mental health service delivery or outreach. Changing stereotypes, prejudices, and uncertainty in provider–patient relations includes creating interventions to change preconceived ideas of either the patient or the provider that may adversely affect the communication or interaction in the clinical encounter.
6. Requiring public and private health systems to more thoroughly collect and report patient outcomes by race, ethnicity, and primary language. Requiring public and private health systems to more thoroughly collect and report patient outcomes by race, ethnicity, and primary language would improve transparency and accountability around health service inequities and the success of related equity-focused interventions. As research progresses in addressing the complexity of the levels and domains that produce health and health care inequities, such data can help equity interventions become more tailored and effective.

These six areas for intervention are just some of many potential ways to increase equity in mental health and substance use disorder service outcomes within the lens of the SCF. The overall goal of the SCF is to help stimulate the research and policy thinking that can foster change for health care systems and communities.

56.8 Criminalization of Persons With Serious Mental Illness

LINDA E. WEINBERGER, PH.D., AND H. RICHARD LAMB, M.D.

The enormously increased presence of persons with serious mental illness in the criminal justice system is one of the great problems of the day. As a result, mental health professionals and society have become much more concerned about the number of persons with mental illness in jails and prisons, as well as the treatment provided to these persons both in such facilities and after release. These issues are relatively recent. Reports of large numbers of persons with mental illness in U.S. jails and prisons began appearing in the 1970s, a phenomenon that had not been reported since the 19th century.

For the purposes of this section, the focus will be on persons with serious mental disorders, that is, schizophrenia, schizoaffective disorder, bipolar disorder, and major depressive disorder. This section discusses the definition of criminalization of such persons and how criminalization came about, the extent of criminalization, the role of the police with regard to persons with mental illness, and the characteristics that are often found in persons with mental illness who have been arrested. The difficulties in treating this population both before incarceration and after release are addressed, including the relationship between serious mental illness and violence and the problems presented by persons who are not able to recognize that they have a major mental illness. The section presents a summation of ways proposed to reduce criminalization. These ways include the following: increased community mental health services that are effective and appropriate to treat persons who are or are at risk of becoming criminalized; better coordination among the police, courts, and mental health professionals; mobile crisis teams; increased mental health training for police officers; and diversion programs for offenders with serious mental disorders to prevent them from entering the criminal justice system, as well as transferring those who are already arrested into the mental health system. The necessary components of treatment for such persons will be discussed. These include having clear goals of treatment and practice, establishing a close liaison between treatment staff and the justice system; understanding the need for structure; having a focus on managing violence; and appreciating the crucial role of case management, appropriate living arrangements, and involving family members. Finally, the section ends with a brief discussion of recently enacted criminal justice efforts to decrease the total number of persons incarcerated and recommends possible strategies to reduce the criminalization of persons with serious mental illness.

MAGNITUDE OF THE PROBLEM

The U.S. prison population for both federal and state prisons was 1,430,800 inmates as of December 31, 2019. In addition, at midyear 2019, there were 734,500 inmates held in county and city jails. Although these numbers reflect a small but continuing decline in the rate of incarcerations, the percentage of jail and prison inmates assumed to be seriously mentally ill (schizophrenia, schizoaffective disorder, major depressive disorder, and bipolar disorder) has been estimated at about 16%. Using these numbers yields an estimate of 346,448 incarcerated persons with serious mental illness in jails, and state and federal prisons. Although the actual number may be somewhat higher or lower, depending on the accuracy of the percentage, these figures represent a substantial number.

Moreover, research has shown that approximately one-fourth of persons with serious mental illness in the community have a history of at least one arrest. The association between serious mental illness and arrest is a widespread phenomenon that has affected both the mental health and criminal justice systems.

Ms. G was a 28-year-old single woman who was diagnosed with schizophrenia at age 22. Prior to her diagnosis, she had a chaotic childhood and adolescence. Her mother abused alcohol and often left her alone in their apartment for days at a time. Ms. G was placed in multiple foster home placements where she frequently eloped, looking for her mother. Attempts at reunification were always unsuccessful due to the mother's continuing neglect and Ms. G's increasing disruptive behavior. At age 18, Ms. G was no longer a ward of the court, and she began living with her 23-year-old boyfriend. She tried to work at fast-food restaurants but found the demands of the job increasingly stressful. She also started to experience paranoid ideas about her coworkers with whom she often fought and heard voices telling her that they wanted to sexually molest her. On one occasion, when she was 20, she fought with her manager and threw his glasses so hard against the wall that they broke. The police were called, and Ms. G was arrested.

During her incarceration, the jail personnel did not recognize that she had a mental illness. She was given probation with no requirement that she obtain psychiatric treatment. She continued to live with her boyfriend until he said she could no longer live with him because of her constant hallucinations and delusions about him. She was now homeless and without money. One day, she walked into a grocery store and stole a loaf of bread and a package of sliced turkey. She was apprehended by a security guard, and the police arrested her. During this incarceration, she was identified as having a mental illness and was treated with antipsychotic medication in jail. Ms. G received probation, but this time was to attend psychiatric outpatient treatment. She went to the community mental health clinic once but did not return because she did not believe she had a mental illness and refused to take any medications.

Shortly thereafter, Ms. G got into a fight with another homeless person and stole his blanket in front of several bystanders who called the police. This led to another arrest where she spent a few months in jail and was again given probation with a condition of outpatient psychiatric treatment. Following her release, she attended outpatient treatment at a mental health clinic for several weeks. Initially, she took her medications which resulted in a dramatic improvement of her symptoms. However, several weeks later, Ms. G stopped taking her medications, wherein her symptoms returned, and she became very threatening to the staff. The court was informed of this, and she was remanded to jail. Prior to her release, Ms. G was encouraged to return to her previous outpatient clinic for treatment. Sometime later, Ms. G appeared at the clinic, but the intake team concluded that her history of nonadherence to psychiatric medications along with her past violent behavior could make her a problem in management beyond the capabilities of the clinic.

A few months later, Ms. G was arrested outside a department store for having stolen a sweater and pushing a customer out of her way. This time, she was charged with petty theft with priors and assault, which was a felony. The judge believed he had no option but to send Ms. G to state prison. Criminalization was now confirmed.

Most outpatient mental health treatment facilities are not structured to successfully treat persons like Ms. G, and, as described in this section, community mental health staff is often reluctant to try.

DEFINING CRIMINALIZATION

Many factors come into play in determining why a person with mental illness is arrested rather than taken to a psychiatric hospital.

Generally, persons who are thought to have committed a felony are arrested and brought to jail regardless of their mental condition. The criminal justice system, charged by society with the responsibility for removing from the community persons accused of committing serious crimes, sees no alternative but to first place the person in custody in a secure setting and then arrange for psychiatric treatment, if necessary. If the person is thought to have committed a serious crime, the police and the criminal justice system generally do not want to place this person in a psychiatric hospital because such persons may well pose a number of problematic issues that cannot be treated and managed adequately by the mental health system and thus place society at risk.

Examples of this may be a person with schizophrenia who was found by the police in possession of a loaded gun; he was brandishing the weapon and threatening others because he believed they were poisoning him. Another person with untreated bipolar disorder was arrested after he drove his car erratically on the street and onto a sidewalk full of pedestrians because he wanted to be recognized for his race-car-driving skills.

For persons charged with misdemeanors, the situation is more complex. In 1972, the term “criminalization of the mentally ill” was first used. It was observed that persons with mental disorders who engaged in minor crimes were increasingly subject to arrest and prosecution. Later, many authors applied the concept of criminalization to persons with mental disorders who were arrested for serious crimes. The distinction between arrest and incarceration of persons with mental illness who have committed minor offenses and those who have committed serious offenses is an important one.

This section takes the position that the term criminalization should be used primarily in connection to persons with serious mental illness who are arrested and incarcerated for minor offenses instead of being placed in the mental health system. However, it should be acknowledged that many persons with serious mental illness who commit serious crimes and enter the criminal justice system might not have engaged in such behavior if they had been receiving adequate and appropriate mental health treatment at that time.

Concern about the inappropriate placement of persons with serious mental illness in the criminal justice system is not new. As far back as 1939, researchers in Europe advanced the thesis that a relatively stable number of persons are confined in any industrial society. Using prison and mental hospital census data from 18 European countries, they found an inverse relationship between prison and mental hospital populations. They theorized that if one of these forms of confinement is reduced, the other will increase. According to this theory, when prison populations are extensive, mental hospital populations will be small, and vice versa. Thus, if there is room in prisons and a shortage of hospital beds, many persons with mental illness who come to the attention of law enforcement might well be directed to the criminal justice system. Recent research in South America is compatible with this hypothesis. As will be seen in this section, this has happened in the United States and other countries; the census of state hospitals has dropped precipitously while the number of persons incarcerated in the criminal justice system has risen to record proportions.

One of the major concerns in present-day psychiatry is that placement in the criminal justice system poses a number of important problems and obstacles for the treatment and rehabilitation of persons with serious mental illness. Even when quality psychiatric care is provided in jails and prisons, the inmate/patient still has been doubly stigmatized as both a person with mental illness and a criminal. Furthermore, jails and prisons have been established to mete out punishment and to protect society; their primary mission and goals are not to provide treatment. The correctional facility's overriding need to maintain order and security, as well as its mandate to implement society's priorities of punishment and social control, greatly restrict the facility's ability to establish a therapeutic milieu and provide all the necessary interventions to treat mental illness successfully. Indeed, such a setting can exacerbate symptoms of mental illness as well as behavior that is noncompliant with the correctional facility's rules; thus, possibly resulting in longer periods of incarceration.

CAUSES OF CRIMINALIZATION

Many factors have been cited as causes for persons with mental illness being placed in the criminal justice system. The most common ones are deinstitutionalization and the unavailability of intermediate and long-term hospitalization in state hospitals for persons with serious mental illness; more formal and rigid criteria for civil commitment; the lack of adequate support systems for persons with serious mental illness in the community, as well as the difficulty such persons coming from the criminal justice system, have in gaining access to community mental health treatment; persons with co-occurring disorders of a serious mental illness and a substance abuse problem being caught up in the war on drugs (being arrested and incarcerated on the basis of the use, sale, and possession of drugs); and a belief by many law enforcement personnel that deviant behavior can be dealt with more quickly and efficiently within the criminal justice system than in the mental health system.

Deinstitutionalization

Beginning in the late 1950s, the inclination to provide hospital beds declined precipitously. This was because of the introduction of psychoactive medications; the development of more efficacious community treatment interventions; the creation of federal programs (e.g., Supplemental Security Income, Social Security Disability Insurance, Medicaid, and Medicare), which would fund community treatment and housing for persons with mental illness; the influence of the civil rights movement; and the high cost of institutionalizing persons with mental illness. For example, in 1955, when the number of patients in state hospitals in the United States reached its highest point, 559,000 persons were institutionalized in state mental hospitals out of a total national population of 165 million (339 beds per 100,000 population). By 2016 (as a result of hospital closures and bed eliminations), the number of persons in state mental hospitals dropped to 37,679 for a population of approximately 324,000,000, or 11.7 beds per 100,000 population. This rate is similar to that found in 1850, when persons with serious mental illness received little care and concern. Their plight led to the beginning of the movement, spearheaded by Dorothea Dix and others, to provide more humane care by treating persons with serious mental illness in hospitals. With respect to freestanding and county facilities that provide acute psychiatric inpatient treatment, the number of available beds has also been dwindling. For example, in California, there were approximately 17.16 beds per 100,000 residents in 2017, a loss of more than 42% per capita since 1995.

Deinstitutionalization has thus been viewed as setting the stage for increasing numbers of persons with mental illness entering the criminal justice system. It must be remembered that the community mental health system was developed in the 1960s and 1970s for persons with mental illness who had more moderate needs. Although deinstitutionalization held the promise of persons with serious mental illness being able to live successfully in the community, that hope was not achieved for a sizeable number of individuals. Part of its failure was attributed to a lack of planning before or during deinstitutionalization, as well as a lack of adequate funding. As a result, communities were not able to provide a sufficient community care system (i.e., housing, medical and psychiatric care, social services, and social and vocational rehabilitation) for the formerly hospitalized patients. Despite this, the majority of deinstitutionalized patients were able to adapt successfully in the community; however, this was not the case for a considerable minority who were arrested and placed in jails and prisons or who became homeless (between one-fourth and one-third of homeless persons have a serious mental illness). Some of these individuals presented challenges in treatment—such as not seeing themselves as mentally ill, not taking their medications, abusing substances, and in many cases, becoming violent when stressed. Many of these persons needed highly structured care to replace that which had been provided to them, albeit imperfectly, in psychiatric hospitals. The flawed implementation of deinstitutionalization would thus appear to be a significant factor accounting for the migration to jails and prisons of many persons with mental illness who otherwise could have been treated with more adequate services in the community or in a hospital. The criminal justice system had become, by default, a safety net for the mental health system.

Restrictive Civil Commitment Criteria

Many believe that more formal and rigid civil commitment criteria have contributed not only to deinstitutionalization but also to an increased number of persons with mental illness in jails and prisons. In 1969, California’s then-novel civil commitment law, the Lanterman–Petris–Short Act, went into effect. Within a decade, every state made similar modifications in their commitment codes. Such a rapid and complete consensus among legislatures is virtually unprecedented. More importantly, it reflected a nearly universal view that past inattention to the rights of persons with mental illness needed to be corrected.

In effect, the new civil commitment laws resulted in three major changes. First, the laws modified the substantive criteria for commitment from more general criteria that simply embodied concepts of mental illness and need for treatment to more specific criteria that embodied either dangerousness to self or others resulting from mental illness or the incapacity to care for oneself. Second, the laws changed the duration of commitment from indefinite and extensive periods to specific and brief periods. Third, the new laws explicitly provided that persons civilly committed have rapid access to the courts, to attorneys, and, in some cases, to jury trials; this access ensured the kinds of due-process guarantees to civilly committed persons that criminal defendants had obtained over the previous decade.

These procedural safeguards and clear commitment standards resulted in fewer, as well as shorter, commitments. Consequently, many individuals with mental illness who otherwise would have been civilly committed by family or others were now left to reside in the community where they might not have been able to care for themselves and control their impulses. Thus, some of these individuals might well have committed criminal acts and entered the criminal justice system.

Lack of Adequate Community Support Systems

Another factor that both leads to and perpetuates the criminalization of persons with serious mental illness is the lack of adequate support systems in the community. An essential part of support systems for these persons is the availability of community treatment resources. Moreover, the type of community mental health resources available may not be suitable for all of the population to be served.

The availability or lack of availability of treatment resources in the community has three important aspects. First, in most jurisdictions, mental health treatment, housing, and rehabilitation resources are insufficient to serve the very large numbers of persons with serious mental illness in the community. For instance, case management has come to be viewed as one of the essential components of an adequate mental health program. However, the mental health system is ill-prepared to provide quality case management services to all persons with serious mental illness who require it, including those leaving jails and prisons.

Second, community mental health resources may be inappropriate for some of the population to be served. For instance, persons with mental illness may be expected to come to outpatient clinics when the real need for a large proportion of this population is outreach services, in which mental health professionals go to see patients where they live. In addition, some service providers may lack the ability to provide the degree of structure required by many persons with serious mental illness. The issue of structure will be discussed later.

Third, persons with mental illness who have been in jail may not be able to gain access to community treatment even when it is available. Many of these persons have been described as resistant to treatment, dangerous, and seriously substance-abusing, characteristics generally not considered desirable by most community mental health agencies and staff. Furthermore, because many of these agencies may not have the capability to provide the needed structure, limit setting, and security and safety for staff necessary to treat these persons successfully, their reluctance to treat them may be appropriate.

A large proportion of persons with mental illness who commit criminal offenses are found to be highly resistant to psychiatric treatment. They may refuse referral, may not keep appointments, may not be adherent with psychiatric medications, may not abstain from substance abuse, and may refuse appropriate housing placements. There is evidence that many of these persons suffer from a disorder called anosognosia (a biologically based inability to recognize that one has a mental illness, and thus a biologically based lack of insight). This is discussed in greater detail later.

Thus, the mental health system finds offenders with mental illness extremely difficult to treat and may be hesitant to serve them. This reluctance may extend to virtually all areas of community-based care, including psychiatric treatment, therapeutic housing, social and vocational rehabilitation, and general social services. Moreover, many offenders with mental illness can be intimidating because of previous violent and fear-inspiring behavior. Treating this group is very different from helping passive, formerly institutionalized patients to adapt quietly to life in the community. Community mental health professionals are not only reluctant but may also be afraid to treat them, especially when measures are not adopted to ensure staff safety. Consequently, these persons are left for the criminal justice system to manage. However, there are outpatient facilities in which structure is provided, security personnel is present, and thus staff is protected, and mental health and criminal justice staff collaborate closely; under such circumstances, many of these persons are successfully treated.

The Role of the Police

The police play an important role in the criminalization of persons with serious mental illness, and this will be discussed in the context of the more in-depth exposition of the police and mental health that follows.

Police and Mental Health. Since the advent of deinstitutionalization and the exodus of persons with mental illness into the community, law enforcement agencies have had an increasingly important function in the management of persons who are experiencing psychiatric crises. The rationale for the police to intervene in the lives of persons with mental illness derives from two common-law principles: the power and the authority of the police to protect the safety and welfare of the community, and the state’s paternalistic or *parens patriae* authority, which dictates protection for citizens with disabilities who cannot care for themselves, such as those who are acutely mentally ill.

The police are typically the first responders in the community to urgent situations involving persons with mental illness. They provide services 24 hours a day, 7 days a week. Therefore, they play a major role as a mental health resource. They are responsible for either recognizing the need for the treatment of an individual with mental illness and connecting the person with the proper treatment resources or making the determination that the individual has committed a type of illegal act for which the person should be arrested. This responsibility thrusts them into the position of primary gatekeepers who determine whether the individual will enter the mental health or the criminal justice system.

With respect to persons with mental illness, police in all states have the power to transport persons for psychiatric evaluation and treatment when there is probable cause to think that they are a danger to themselves or to others because of their mental condition. As a result, law enforcement officers have assumed the role of “street-corner psychiatrist” by default. Many officers have grown accustomed to this role and consider it one of their duties; however, other officers do so reluctantly, and some do it with resentment. A major problem with having to fulfill this role is that the police have little training in performing this kind of triage. This lack of training is one of the factors that has played an important part in the criminalization of persons with mental illness. The training of law enforcement officers is discussed later in the subsection entitled *Diverting Persons with Mental Illness from the Criminal Justice System.*

The police have a great deal of discretion in the exercise of their duties, including determining what to do when they encounter a person with acute mental illness in the community. In most cases, the police use informal tactics, such as trying to “calm” the person or taking the person home. This practice has been referred to as “psychiatric first aid.” In situations that cannot be handled informally, the police may have to take persons with mental illness to hospitals or jails.

In some cases, however, public policy limits the police officer’s discretionary power. For instance, if the person with mental illness is alleged to have committed a major crime, the disposition is clear—that person is taken to jail because of the seriousness of the offense.

Often, the interaction between the police and the person with mental illness is initiated by citizens. In such cases, the citizens’ demands also may come into play and limit the discretion of the police. For example, many retail stores have a policy that anyone caught shoplifting should go to jail, and store managers are instructed to make a citizen’s arrest and call the police without exception. In another kind of situation, people who have just been assaulted by a person with psychosis frequently are not inclined to be sympathetic to their assailant, even when a mental disturbance is evident. The result may be an angry citizen insisting that the person be arrested and taken to jail.

Police and Criminalization. As discussed previously, the police play an important role in the criminalization of persons with serious mental illness. Even when the police consider the behavior of a person who has come to their attention to be the result of a mental illness, they may encounter a number of problems and irritants when trying to place the person in an inpatient psychiatric facility. For example, there may be long waiting periods in psychiatric emergency rooms during which police officers cannot attend to other duties. Mental health professionals may question the judgment of the police and refuse admission, or they may admit for only a brief hospital stay a person who just a short time before constituted a clear menace to the community.

However, the police are well aware that if they arrest a person with mental illness, that person will be dealt with in a more systematic and predictable way under the criminal justice system. The individual will be taken into custody; it can be hoped that the person will be seen by a mental health professional attached to the court or in jail and will probably receive psychiatric evaluation and treatment. Thus, an arrest is a response with which police are familiar, one over which they have more control and one that they believe will lead to an appropriate disposition.

Although a person with mental illness suspected of committing a serious crime will most certainly be arrested and transported to jail, a number of factors in addition to those just mentioned have been proposed to explain why a person with serious mental illness suspected of committing a minor offense is arrested rather than taken to a hospital. A person who appears mentally ill to a mental health professional may not appear so to police officers, who, despite their practical experience, have not had sufficient training in dealing with this population and are still laypersons. In addition, mental illness may appear to the police as simply alcohol or drug intoxication, especially if the person with mental illness has been using drugs or alcohol at the time of the interaction with the police. Moreover, in the heat and confusion of an encounter with the police and other citizens, which may include forcibly subduing the person with mental illness, signs of mental illness may go unnoticed. Furthermore, studies have shown that the occurrence of violence at the time of a police encounter increases the chances that the person with mental illness will be taken to jail.

Another instance is when law enforcement officers may charge persons with mental illness with a misdemeanor and take them to jail if they think that no other appropriate alternatives are available, a practice that has been referred to as “mercy booking.” Thus, the scarcity of psychiatric inpatient beds and/or limited community mental health services may be a factor contributing to the criminalization of persons with serious mental illness.

MENTAL ILLNESS AND VIOLENCE

In countries that have experienced mass deinstitutionalization since the late 1960s, studies have shown that persons with serious mental illness were more likely to commit criminal offenses and even more likely to commit violent offenses than the general population. This growing body of evidence demonstrates a relationship between mental illness and violence, primarily among persons who do not take their medications and are psychotic. Substance abuse has also been shown to increase the risk of violent behavior, particularly in combination with serious mental illness. Thus, nonadherence to medication, acute psychosis, and substance abuse account for most of the increased violence among persons with serious mental illness. For instance, one study examined persons with serious mental illness in the United States who were arrested over a 10-year period and found that more than one-third were arrested for violent crimes (assault and murder), and more than one-fifth were arrested for drug offenses.

The relationship between serious mental illness and violence is most easily seen in relatively nonviolent societies, such as in Scandinavia. The Scandinavian countries maintain centralized case registries that record comprehensive data on everyone born in the country or who immigrates there. Included in this wealth of data are psychiatric registers and national police registers. In Denmark, the psychiatric registry includes data such as admissions to psychiatric wards, dates of admission and discharge, and discharge diagnoses. There is also a national police register that records all arrests and convictions, as well as information on all criminal proceedings. These registers allow for the computerization and analysis of the data.

For instance, it was found that males in Denmark with a serious mental disorder who were admitted to a psychiatric hospital by age 44 years represented only 5% of the total population of males but were responsible for about 30% of all the violent offenses committed by males. Likewise, female mental patients in Denmark constituted about 5% of the female population but were responsible for 50% of all the violent offenses committed by females.

In another Danish study, the risk of violent offending was found to be 4.6 times higher for male subjects with schizophrenia and two times higher for those with affective psychoses than for male subjects who were never admitted to a psychiatric ward. For female subjects with schizophrenia, the risk was 23.2 times higher, and for those with affective psychoses, the risk was 3.9 times higher than for female subjects who were never admitted to a psychiatric ward.

Similar findings were noted in Sweden in a study that examined all 15,117 individuals who were born in Stockholm in the same given year. They were evaluated through case registries 30 years later to determine how many were diagnosed with a serious mental illness and were convicted of a violent crime. It was found that 15% of the men and 6% of the women who had a major mental disorder were convicted of a violent offense. A recent study of persons with mental illness in Sweden who were prescribed antipsychotics or mood stabilizers found that violent crime dropped by 45% for those receiving antipsychotics and 24% for those receiving mood stabilizers.

It has been asserted that violent behavior by a subgroup of persons with serious mental illness increases community stigmatization and rejection of persons with mental illness generally. These violent episodes, often highly publicized, may result in the association of mental illness with violence in the public’s mind. Such stigmatization can result in the public’s reluctance to support funding for adequate mental health services for persons with mental illness. Moreover, there may be less tolerance for integrating persons with mental illness into community housing and finding them appropriate employment. It will be difficult to reduce the stigma of mental illness and its consequences until the violence of this subgroup is addressed. Furthermore, to safeguard the welfare of persons with serious mental illness, as well as the safety of the public, mental health professionals, and society must not ignore the evidence that mental illness is associated with some increased risk of violence.

Although there is a subgroup of persons with serious mental illness who are violent, it is extremely important to take into consideration data that demonstrate that an even larger group of persons with serious mental illness are the victims of violence. For example, in a review of studies of violent victimization, 35% of persons with serious mental illness were victims of violence within the last year. For persons with serious mental illness, their victimization by violence tends to receive less public attention than the violence that is perpetrated by them.

Anosognosia

Anosognosia is a biologically based inability to recognize that one has a mental illness and thus is a biologically based lack of insight. Researchers have identified various parts of the brain (e.g., ventricles, frontal and temporal lobe subregions, medial temporal and inferior parietal regions, and subcortical structures) where damage is likely to result in anosognosia. Impaired insight may be mediated by deficiencies in conceptual organization and the lack of flexibility in abstract thinking. Generally, lack of insight that one has a serious mental illness is one of the risk factors for violence in persons with schizophrenia, thus demonstrating a relationship between poor insight and violent behavior.

The importance of anosognosia is demonstrated by a study investigating 907 adults who met the criteria for psychotic and affective disorders and received public mental health services. This study found that 26% of these persons with serious mental illness reported being arrested or violent in the last year. These individuals were significantly more likely to deny needing psychiatric treatment.

Overall, these findings suggest that many of the people who are most in need of psychiatric treatment are the least likely to believe that they need it. Treatment nonadherence is a key barrier to implementing evidence-based interventions. Several studies confirm that treatment involvement is related to a lowered risk of arrest and violence in persons with serious mental illness by reducing their psychiatric symptoms and substance abuse. Interventions to improve insight and treatment adherence in this population are warranted and needed.

SOME CHARACTERISTICS OF PERSONS WITH SERIOUS MENTAL ILLNESS WHO ARE

INCARCERATED

It is known that there are very large numbers of persons with serious mental illness in jails and prisons. What is known about them in terms of their criminal histories and legal status, the psychiatric services they use while incarcerated, and the challenges they might present in psychiatric treatment after release?

Two studies attempted to answer these questions. The first was a retrospective study of inmates with serious mental illness who were arrested and placed in a large, urban county jail. It should be noted at the outset that these findings do not necessarily represent what one would find in a similar study conducted in state and federal prisons or even in other jails. This study revealed that 76% of these inmates required and received psychiatric inpatient care or its equivalent for part of their time in jail during the current offense. Clearly, a large number of people with serious mental illness are receiving their acute psychiatric inpatient treatment in the criminal justice system rather than the mental health system.

With respect to these inmates' history before the current arrest, at least 92% were known to be nonadherent to psychiatric medications, 94% had prior arrests, 72% had prior arrests for violent crimes, and 76% were known to have a history of substance abuse. Given these data, in addition to the fact that three-fourths of these inmates required inpatient psychiatric care in the jail, it would appear that the jail had acquired the responsibility of handling many persons with serious mental illness who were among the most difficult and expensive to treat.

Another study conducted on individuals who had a serious mental illness and were transferred from jail to a psychiatric inpatient unit found that 75% had a history of physical assault in the community, 72% engaged in substance abuse, and 78% were generally nonadherent to medications. Findings revealed that poor insight into illness and nonadherence to medications were associated independently with violence toward others.

That such large percentages of persons in both studies had a history of being nonadherent to psychiatric medications suggests that treatment on re-entry into the community should include such measures as evaluation and supervision by mental health courts, assertive community treatment (ACT), and assisted outpatient treatment (AOT) (see later discussion).

Moreover, short-term, intermediate-term, or long-term hospitalization may be needed for many.

It was observed in these studies, as it frequently is in jails generally, that a number of persons with serious mental illness are arrested when it appears that their offending conduct was due primarily to their illness. The nature and circumstances of the offense suggest that these persons should have been psychiatrically hospitalized instead of being taken to jail. The following two cases serve to illustrate this point.

A person with psychotic symptoms and a previous diagnosis of Schizophrenia was walking in circles, talking to himself, and then urinating outside a grocery store; he was arrested and charged with indecent exposure. Another person with manic and paranoid symptoms was panhandling at a gas station and yelling that a customer was stealing his money, whereupon he pushed this customer and others. The attendant at the gas station called the police, who arrested him for assault. These individuals would probably have been better served if they were taken to a psychiatric hospital and placed under the jurisdiction of the mental health system rather than being arrested and placed in jail. Incarcerating such persons in settings where it is difficult to provide good treatment, such as jail, does not appear to meet the needs of society by protecting society from dangerous people. Moreover, efforts to reduce the possibility of recidivism by these persons can generally be accomplished by treatment and management within the mental health system.

Using Cognitive Behavioral Therapy to Address Antisocial Characteristics

Some professionals have attributed criminal acts by many persons with serious mental illness primarily to the individual's criminal characteristics. These professionals believe that although there are incarcerated individuals who may have a serious mental illness, many of them are in correctional facilities largely because of their antisocial attitudes and a lack of problem-solving and self-control skills that contribute to their criminal behavior. Consequently, a primary intervention suggested to reduce recidivism is to focus on the antisocial cognitions of these persons.

Indeed, a number of persons with serious mental illness in the criminal justice system may have antisocial tendencies, often to the extent of justifying a diagnosis of antisocial personality disorder. While cognitive-behavioral therapy (CBT) may be a necessary component of the treatment regimen for many such offenders in reducing their recidivism, if such persons' thinking and judgment are impaired by their untreated psychotic and manic symptoms, they may not be able to profit from CBT interventions. Therefore, if CBT is to be effective, it should be combined with psychiatric treatment.

Diverting Persons with Mental Illness from the Criminal Justice System

With the very large and increasing number of persons with serious mental illness found in jails and prisons, there have been large-scale efforts to divert them from the criminal justice system to the mental health system. Various stakeholders are involved or affected by diversion: criminal justice personnel, mental health service providers, victims, the arrested individuals' families, and the community-at-large.

Diversion, before the person is actually booked into jail or prebooking diversion, is exemplified by large-scale efforts to create community mobile crisis teams of police officers and/or mental health professionals. In addition, coordination between police and mental health professionals, as well as mental health training for law enforcement officers, may help in reducing arrests

Diversion after booking takes a variety of forms. These include specialized mental health courts, also known as problem-solving courts, that are therapeutically oriented to handle issues related exclusively to offenders with mental illness. Mental health consultation with other courts may also assist the judge by offering recommendations for treatment in lieu of incarceration.

Mobile Crisis Teams. Psychiatric emergencies are managed effectively in communities in which close formal liaisons between law enforcement and mental health agencies are established. These arrangements help to facilitate the resolution of crises of persons with mental illness in the field without the need to resort to hospitalization or incarceration. When resolution in the field is not possible, the existence of these liaisons increases the number of persons with mental illness who are referred to the mental health system rather than jailed, thus reducing criminalization. For those who need psychiatric hospitalization, these relationships tend to increase the rate of acceptance by hospitals.

Different strategies have been developed to provide a mobile team of police, mental health professionals, or both to respond in the community to persons with mental illness who are in crisis. The following are two of these strategies that are used most commonly.

An increasing number of jurisdictions use sworn police officers who have special and extensive mental health training to provide crisis intervention services as part of crisis intervention teams (CIT programs) and to act as liaisons to the mental health system. This approach is often referred to as the “Memphis Model” because it was developed in Memphis, Tennessee. These specially trained officers may deal with mental health emergency situations on-site or act as consultants to the officers at the scene. This model places a heavy reliance on psychiatric emergency services that have agreed to a no-refusal policy for persons brought to them by the police. Although this strategy has a close liaison with mental health, it does not require the actual participation of mental health professionals in the field.

Another model that some jurisdictions use deploys teams composed of both specially trained sworn police officers and mental health professionals employed by the local community mental health department. These teams have been shown to be effective in resolving emergency situations in the community involving persons with mental illness and in diverting them to the mental health system rather than to the criminal justice system. An advantage of this model is that the mental health professionals on the team may have access to the person’s documented mental health history. Having such data available is an important factor that can help the team better understand the person’s mental condition and make more informed decisions.

The major goals of both of these specialized mobile crisis teams are to resolve the crisis and reduce criminalization. Studies evaluating such teams found arrest rates ranging from 2% to 13% (with an average of less than 7%), in contrast to an arrest rate of 21% for contacts between nonspecialized police officers and persons who were apparently mentally ill. This finding lends credence to the idea that a specialized response lowers the incidence of inappropriate arrests.

Regardless of whether police officers act as part of a team with members of the mental health system in dealing on-site with emergency situations, or police act on their own in dealing with these situations, it is imperative that they obtain all available information about past police contacts with the individual when mental illness is thought to be present. Such information may include aspects of the person’s actions during previous police contact, such as suicide attempts and violence, and how the previous contact was resolved.

A crucial part of developing and maintaining any specialized mobile response team is that a rigorous and ongoing evaluation of the program must be conducted. For instance, response times—the time from the call to the arrival of the team on the scene—should be measured on a routine basis. If response times are too long, police officers in the field tend not to call on the mobile teams. The teams’ arrest rates, and the mental health alternatives they choose, need to be evaluated regularly to be sure that appropriate dispositions are being made and that mental health facilities are cooperating with these efforts.

Increased Coordination and Need for Training. From the standpoint of the police, it is clear that officers need and want rapid on-site assistance from mental health professionals when they are called on to deal with difficult or complex situations involving persons with mental illness who are acutely psychotic, behaving bizarrely, or exhibiting violent behavior, or for persons who have attempted suicide or made a suicide gesture. Similarly, mental health professionals who are working as members of psychiatric emergency teams without police support may feel ill-equipped to handle such individuals in the field. Thus, it has become increasingly apparent in recent years that when persons with mental illness in the community are in crisis, neither the police nor the emergency mental health system alone can serve them effectively and that it is essential for the two systems to work closely together in their planning, implementation, and continuous problem-solving.

Training of Police. Most police departments provide some type of officer training in mental illnesses; however, training in how officers should respond to persons with mental illness who are in crisis is less common. It has been found that when police respond to crisis situations, the risk of injury or death for individuals with serious mental illness is 16 times greater than for those with no serious mental illness. Consequently, mental health training is needed for all police officers, not just for those who are part of the specialized mobile crisis teams. Benefits of training include assisting the police in their interactions with persons who have serious mental illness as well as the potential to reduce injuries.

Training for police officers about mental health issues and individuals with mental illness should begin in police academies as a regular part of the curriculum. This training should focus on enhancing the understanding of mental illness by law enforcement personnel. Furthermore, it should aim at increasing their knowledge about such mental health issues as how to recognize mental illness, how to handle violence or potential violence among persons with mental illness, what to do when a person is threatening suicide, and when to call the specialized mobile crisis team. In addition, information should be provided as to what mental health resources are available, both inpatient and outpatient, and when a person should be arrested and incarcerated as opposed to being taken to a mental health facility.

For the training to be successful and relevant, trainers should come from both the mental health and criminal justice systems. Trainers from the mental health system should be persons who have experience with crisis intervention in the field and/or in crisis centers, as well as knowledge and field experience relating to the criminal justice system. These mental health professionals must understand and appreciate the challenges and risks that law enforcement officers experience every day in the field. Whereas trainers from the criminal justice system already have credibility with their trainees and knowledge about such issues as officer safety and enforcement protocols that noncriminal justice system persons would not have.

Another important issue to consider when law enforcement officers encounter persons with mental illness is how the individual perceives the officers. Persons with mental illness may have negative attitudes toward the police; they may be fearful of police, believing that the officers do not listen to them, and may use force against them. Such perceptions can lead to dangerous escalating interactions. Consequently, the attitudes and behaviors of both the officer and person with mental illness can influence the outcome of their contact. Understanding how persons with mental illness may perceive law enforcement officers, particularly if they had a previous negative experience with police, is essential.

It needs to be emphasized that mental health training should be an ongoing process, not only for police officers in special mental health crisis teams but also for all police officers.

MENTAL HEALTH SERVICES AFTER ARREST

To reverse criminalization, it is extremely important to identify persons with mental illness as quickly as possible after they have been arrested and placed in jail. A facility may routinely screen all incoming detainees for serious mental disorders. Initial screenings may be conducted by custody personnel who notice the inmate engaging in odd or bizarre behavior. Medical/psychiatric questionnaires are also used in many correctional institutions as screening devices. Such questionnaires typically consist of less than 20 questions aimed at identifying inmates who may need psychiatric care. Those individuals who endorse items on the questionnaire or who appear to have a mental illness may then be seen by a clinician for a more extensive evaluation to determine what type of housing and/or mental health treatment they should receive while incarcerated. Even more important, if the person is one who should have been treated in the mental health system in the first place, discharge planning should begin as soon as possible after an arrest.

Given the large numbers of persons with serious mental illness who are arrested, jail administrators should be encouraged to negotiate programmatic relationships with mental health agencies to provide multidisciplinary teams of clinicians to work in the jail setting. These teams should include psychiatrists so that psychoactive medications can be prescribed. The teams should be established inside jails to provide short-term crisis intervention, treatment, referral to a psychiatric hospital if necessary, and discharge planning. Such information can be useful in helping the judicial system make decisions concerning the person’s legal disposition.

Mental Health Courts

Post-booking diversion strategies are being used increasingly by special courts called mental health courts. The first mental health court that received national attention was established in Broward County, Florida, in 1997, and since then, the number of mental health courts in the United States has increased greatly. Initially, these courts were set up to hear cases of persons with mental illness who were typically charged with misdemeanors. In recent years, these courts have increased their purview to serve persons with mental illness charged with felonies. In mental health courts, all the courtroom personnel (i.e., judge, prosecutor, defense counsel, and other relevant professionals) have experience and training in mental health issues and available community resources. These mental health courts have a particular set of characteristics: they hear specialized cases involving defendants with mental illness; they use a nonadversarial team of professionals (e.g., judge, attorneys, and mental health clinician); they are linked to the mental health system that will provide treatment, and they use some form of adherence monitoring that may involve sanctions by the court.

Underlying the concept of mental health courts is the principle of therapeutic jurisprudence, which emphasizes that the law should be used, whenever possible, to promote the mental and physical well-being of the people it affects. The concept of therapeutic jurisprudence operates on the belief that the application of the law can have therapeutic consequences. It should be emphasized that therapeutic jurisprudence does not diminish the importance of public safety, which is fully considered by the court.

In a system characterized by therapeutic jurisprudence, people with serious mental illnesses charged with crimes may be diverted into programs designed to address their treatment and service needs rather than simply being incarcerated with their treatment needs being neglected. Even individuals with serious mental illnesses convicted of serious crimes can be provided with humane and appropriate treatment while incarcerated. Generally, mental health courts facilitate linking offenders with serious mental illness to appropriate needed services and supports on discharge from jail in order to enable them to successfully re-enter their communities.

Mental health courts were developed as a strategy to divert persons with mental illness from the criminal justice system into the mental health system. When offenders with mental illness are booked into jail, their case is usually handled by mental health courts in one of two ways. In the first situation, the prosecution of their cases may be postponed by the judge so that they may be involved in a specified treatment program run by the mental health system.

If they successfully complete the program, their criminal charges are dismissed (or, in some cases expunged), and the individuals are no longer under the jurisdiction of the criminal justice system. If they fail to complete the treatment program successfully, the charges are reinstated, and the criminal proceedings resume. In the second case, the offender with mental illness offers a plea of guilty or *nolo contendre,* which is accepted by the court. The person is sentenced (e.g., sentenced to 180 days in jail, which may be held in abeyance) and given probation, which includes treatment by the mental health system as a condition of probation. If the person is nonadherent with treatment or other probationary conditions, probation may be withdrawn, and the sentence imposed. There is evidence that these types of jail diversion may reduce recidivism for persons with serious mental illness.

The mental health court system works in a collaborative effort to devise and implement a treatment plan that includes not only medications and therapy but also housing, social and vocational rehabilitation, income assistance, and family support if possible. These interventions are to address the individual's mental illness and reduce their risk of recidivism. Research has suggested that a factor contributing to reducing recidivism and improving clinical outcomes is when the court and mental health personnel work as a "team" to coordinate and provide services. Clearly, the quality of services plays an influential role in the success of mental health courts. However, there may be unforeseen limitations of these programs with respect to available resources. That is, there are often insufficient community psychiatric treatment, rehabilitation, and housing capabilities in the existing mental health system to accommodate those persons with mental illness who are diverted from the criminal justice system. Another issue that has already been discussed is that many community resources are not appropriate, adequate, or willing to serve a large proportion of those who are diverted from the criminal justice system. Not surprisingly, there is research evidence that this lack of appropriate resources to which diverted persons can be referred results in recidivism.

Another problem resulting from the services recommended by these courts for offenders with mental illness is the possibility that they might be provided at the expense of programs for persons with mental illness who have not committed crimes. When this happens, an undesirable situation may be set up whereby committing a crime offers the patient with mental illness the best chance of getting psychiatric treatment.

These specialized mental health courts have been given high priority because they appear to be part of the answer to the problem of criminalization. However, for these diversionary programs to be truly effective and not overwhelm the already existing limited budgets of the departments of mental health, the treatment to which the courts have referred the offender with mental illness should be funded by additional monies. These monies could come, at least in part, from savings in the criminal justice system, which would no longer have to incarcerate and treat these persons.

The Importance of Mental Health Consultation to the Court

Consultative arrangements with mental health professionals may help to correct a problem that involves the computerized criminal histories, or "rap sheets," available to the court of persons with serious mental illness. Criminal justice personnel, such as prosecutors, probation officers, and parole officers, access the person's criminal history. It is important to consider what effect this may have on the court's decision-making regarding the disposition of the individual when there is no mental health input. These computerized criminal histories seldom include a narrative as to what really happened during the previous arrests. Even when a person with serious mental illness commits nonserious offenses, a series of them can result in a lengthy computerized criminal history for the individual. Thus, when such individuals subsequently appear in court, they may look like habitual criminals when their criminal histories are accessed.

By providing mental health evaluation and consultation, it may become clearer in these instances that these are persons with serious mental illness who were not receiving adequate treatment and who repeatedly acted in an inappropriate and/or aggressive manner when stressed, which caused them to come to the attention of law enforcement officers and be arrested. An example would be a woman with a history of bipolar I disorder who has a history of arrests for crimes including disturbing the peace (playing loud music throughout the early morning hours), destroying public property (defacing doors in a county building), resisting arrest for disorderly conduct (screaming at her neighbors in the middle of the night), and hitting a man on the bus whom she falsely believed was making sexual overtures toward her. Her most recent arrest was for throwing rocks at her neighbor because she mistakenly believed he was spying on her while she was taking a shower. Without the input of a mental health professional to evaluate this individual, the judge might believe that she should be incarcerated instead of referred to a hospital or other psychiatric treatment. Thus, this person with serious mental illness would continue to be criminalized.

OUTPATIENT TREATMENT TO REVERSE OR PREVENT CRIMINALIZATION

To decriminalize persons with serious mental illness, it is necessary to find ways to help them become stabilized outside of jails and prisons and, to the extent possible, not enter the criminal justice system at all. Thus, the community treatment of persons with serious mental illness who are or may become offenders has developed into an increasingly important and urgent issue. There are greatly increased numbers of persons with serious mental illness who find their way into the criminal justice system, are released into the community, and unfortunately, revolve back into the criminal justice system.

A study examined all persons (*N* = 79,211) who were incarcerated in one state's prison system during a 1-year period. Ten percent were diagnosed as having major depressive disorder, bipolar disorders, schizophrenia, or nonschizophrenic psychotic disorders. Twenty-one percent of these inmates with serious mental illness were currently incarcerated for a violent offense. These inmates also had a statistically higher percentage of assault, robbery, and property offenses than the inmates who had no psychiatric disorder. In addition, inmates with serious mental illness were far more likely to have a history of incarceration than those without a serious mental illness. As a result of this study's findings, the authors acknowledged that there was a need to not only develop programs to treat persons with serious mental illness in correctional facilities but also to find effective alternatives to incarceration in the community, including pre- and postbooking diversion programs, increasing discharge planning or continuity of care programs, drug and alcohol screening and treatment, and access to psychiatric inpatient treatment.

The purpose of this section is to review community treatment of persons with serious mental illness who, without treatment, have been or might become criminalized and to discuss the principles of treating this population as viewed generally by clinicians who conduct such treatment. This includes those who specialize in forensic mental health care. In addition, because such large numbers of persons with serious mental illness have become criminalized and then released into the community, many mental health professionals who previously may not have been involved in treating offenders with mental illness are now finding themselves with treatment responsibilities for this population.

Probably, many criminalized persons with serious mental illness can be treated at mainstream mental health clinics on their release from jails and prisons. This is exemplified by nondangerous persons with psychosis who are arrested for minor crimes, such as disturbing the peace or not paying for a meal in a restaurant, and who are taken to jail rather than the more appropriate disposition of taking them to a hospital. Another example would be individuals with serious mental illness who committed felonies and were sent to prison but are nondangerous, such as a person with bipolar disorder who was sentenced to prison for forging checks.

However, it must be recognized that there are many who are discharged from correctional institutions who have multiple problems that cannot be adequately treated in traditional community-based facilities. An example of this would be persons with serious mental illness who have a history of dangerousness; placing such persons in a traditional community clinic often results in exacerbations of their illness and acts of violence that lead to rehospitalization or reincarceration. For these individuals, it is important to have special, highly structured clinics staffed by professionals who understand dangerous offenders with mental illness and their treatment. Moreover, adequate security in such clinics is essential; this should include metal detectors, the presence at all times of trained security personnel, and emergency alarm buttons within easy reach of the mental health staff. These clinics may be in the mental health system, with the patients' treatment monitored by the criminal justice system (e.g., court and/or department of probation), or the clinics may be an actual part of the criminal justice system (e.g., run by parole departments).

Treatment of Co-Occurring Disorders

It is estimated by professionals and other personnel in the criminal justice system who are knowledgeable about incarcerated persons with serious mental illness that at least three-fourths of them also meet DSM-5 criteria for Substance Use Disorders. Clearly, if treatment after release is to be successful, both the mental illness and the substance abuse must be addressed. These services should be integrated into the community, and it is generally held that the same clinical personnel should provide and coordinate both mental health and substance abuse treatments. Treatment of co-occurring disorders very frequently needs to be a long-term process.

Assisted Outpatient Treatment

Another important treatment modality that is available in almost all states is AOT, often called outpatient commitment. AOT is a court-ordered civil commitment in which the patient is not under the jurisdiction of the criminal justice system. Rather, AOT is initiated by the mental health system to ensure that persons with mental illness and a history of hospitalizations or violence participate in services in the community that are appropriate to their needs. AOT is for persons with mental illness who can live in the community with the help of family, friends, and mental health professionals but are resistant to psychiatric treatment, including medications. Without such treatment, they may relapse and become violent and/or dangerous to themselves and require hospitalization. Because of these characteristics, this population is also prone to be arrested, incarcerated, and criminalized. To prevent decompensation, which may result in hospitalization or criminalization, and to help these persons stabilize in the community, such at-risk individuals are ordered to participate in outpatient psychiatric treatment, with their progress closely monitored by the court.

When AOT is successful, it is because there is usually a requirement that it be accompanied by an intensive and proven form of community treatment, such as ACT or forensic assertive community treatment (FACT). ACT is a community-based program with mobile mental health treatment teams that provide an array of treatment, rehabilitation, and housing services that are available 24 hours a day. FACT is similar to ACT but also includes legal leverage via collaboration with the criminal justice agencies in an effort to reduce recidivism. The goal of ACT and FACT is to help persons with serious mental illness stay out of the hospital and develop skills for living in the community. It should be noted that AOT, ACT, and FACT are evidence-based practices; that is, they have been shown to be effective, using scientifically valid studies.

There are many who believe that the widespread use of AOT would reduce the criminalization of persons with serious mental illness because it mandates treatment for individuals who otherwise are likely to be arrested and enter the criminal justice system.

Challenges of Mandatory Outpatient Treatment

Individuals in AOT with serious mental illness, as well as those who have committed criminal offenses, represent a challenge to outpatient clinicians. The problem lies not only in ensuring safety of the community but also in working with individuals who may be resistant to treatment.

A large proportion of persons with serious mental illness who commit criminal offenses have a history of being highly resistant to psychiatric treatment before their involvement in the criminal justice system; this is also true for persons who are considered to need AOT. They may have refused referral, may not have kept appointments, may have been nonadherent with psychoactive medications, and may have refused appropriate housing placements. Many have anosognosia and are not able to recognize that they have a mental illness.

For many offenders with mental illness, problems of resistance may continue after release from incarceration, which can place them at risk to the community. This is a fact that the treating professional must always keep in mind.

The mental health system finds many resistant persons with mental illness extremely difficult to treat and is often reluctant or unable to serve them. The reluctance becomes even greater after these persons have committed offenses, become involved in the criminal justice system, and are referred to community agencies. The disinclination to serve these persons extends to virtually all areas of community-based care, including therapeutic housing, social and vocational rehabilitation, and general social services. Many offenders with serious mental illness are intimidating because of previous violent, fear-inspiring behavior. Treating them is very different from helping submissive, nonthreatening, formerly institutionalized patients to adapt quietly to life in the community. Thus, community mental health professionals not only are reluctant but also may be afraid to treat offenders with mental disorders. In addition, professionals may work in treatment facilities that do not adequately provide for staff safety, do not possess the authority and leverage of the criminal justice system, and do not provide treatment interventions with an adequate structure for this population. The reluctance to treat potentially dangerous persons in such treatment facilities may be warranted. Another issue related to mental health professionals' reluctance to treat such individuals is their belief that they do not have adequate training and experience in risk assessment to ensure public safety. As discussed later, outpatient programs need to increase their ability to treat persons who do not see themselves as having a mental illness and/or have a potential for dangerous behavior.

Another important obstacle to receiving outpatient treatment for persons with serious mental illness who are in AOT or are offenders is that community mental health resources may be inappropriate. For instance, these persons may be expected to come to outpatient clinics when the real need for many in this population is for outreach services where professionals come to them.

As discussed later, a crucial part of the treatment of these persons with serious mental illness is adequately and appropriately structured and supportive therapeutic housing arrangements.

When the Criminal Justice System Is Involved

When the criminal justice system is involved in the outpatient treatment of offenders with serious mental illness, a need exists for a clear understanding of the criminal justice system's perspectives and goals. These perspectives and goals include an emphasis on concerns about public safety, control of violence, extensive use of authority, and close cooperation between the mental health and criminal justice systems.

There are a variety of circumstances under which offenders with mental illness in the community remain under the jurisdiction of the criminal justice system. One such group consists of individuals given probation by the court that includes a condition of outpatient treatment, with the possibility of being sent to jail or prison if they are nonadherent to treatment. Another consists of individuals released from prison who are referred for treatment by their parole officer with the understanding that failure to comply may result in a revocation of parole and return to custody.

Treatment Under the Jurisdiction of the Criminal Justice System

For those offenders who are mandated by the court or an agent of the criminal justice system (probation officer, parole officer) to attend outpatient treatment, the criminal justice system retains jurisdiction over the individual. In such situations, both the offender with mental illness and the therapist must satisfy legal requirements, such as regular attendance and periodic progress reports. The patient must comply with legal restrictions, such as abstinence from drugs and alcohol. Therapists who treat such individuals are often asked to provide reports to the court, probation officer, or parole officer on the patient's treatment, including issues such as attendance, diagnosis, progress, and prognosis.

Both the criminal justice system and forensic clinicians generally expect that offenders with mental illness given treatment will gain some understanding of the role of their psychiatric disorder in the past and potential future dangerous behavior and that they will avoid behavior or situations that might increase the risk of criminal activity or deterioration in their clinical condition. Moreover, both society and the criminal justice system expect that treatment will be conducted under conditions that can, to the greatest extent possible, ensure safety of the community.

Thus, a balance must exist between individual rights and public safety. However, it has been argued that courts place a greater emphasis on the potential dangerousness of the offender with mental illness than on the individual's rights. In so doing, the courts place the burden on the offender to demonstrate that they no longer pose a danger to the community. Consequently, the person's risk of violence, to a large extent, dictates whether such an individual will be placed into and remain in the community.

Outpatient treatment for offenders with serious mental illness is not designed to make presently dangerous individuals nondangerous. Rather, the criminal justice system presumes that offenders with mental illness placed in outpatient treatment will not be dangerous to others while under supervision and treatment in the community. A primary concern in the outpatient treatment of these individuals is to assess any changes in the mental condition that may indicate violence and to reduce the potential threat of harm. Therefore, features that contribute to a patient's risk of harm are addressed first in treatment. The psychiatrist must assess dangerousness and incorporate this assessment into an intervention strategy. Thus, outpatient clinicians must have as great possible an understanding of each patient's potential for violence as a function of their history and psychiatric condition. Moreover, the clinicians should feel comfortable and qualified to engage in such assessments.

In contrast, in nonforensic psychiatric treatment of nonviolent persons with serious mental illness, the primary focus is usually on alleviation of symptoms. Clinicians who treat offenders with mental illness need to recognize that they have assumed responsibility not only to the patient but also to society in ensuring the patient's safety in the community. This responsibility is not as central when clinicians are treating nonoffenders.

Identifying a Treatment Philosophy

To work effectively with this extremely difficult group of psychiatric patients, both those in AOT and those who are offenders, the necessity of identifying and articulating a treatment philosophy of both theory and practice should be emphasized. This philosophy, as already mentioned, should strike a balance between individual rights and public safety and use treatment services that take both into account. A reality-based treatment philosophy is needed, one that includes clear treatment goals, with attention paid to goals expressed by the patient; a close liaison with the court or other criminal justice agency monitoring the patient, including access to each patient's database from the criminal justice and mental health systems; and an emphasis on structure and supervision.

The importance of psychotropic medications for this population with a serious mental disorder, most of whom have problems centering on control, cannot be overemphasized. In many cases, if adherence is to be ensured, the patient must live in a community facility in which each dose is dispensed by staff.

A clear conception of the clinical uses and therapeutic value of authority appears to be a cornerstone of successful community treatment for persons with serious mental illness in AOT or for those who are offenders. When treatment is effective, the staff is not ambivalent about the use of authority. They are comfortable about insisting consistently and reasonably that the imposed conditions be followed, monitoring patients' adherence to prescribed psychiatric medications, and monitoring patients to detect the use of alcohol or illegal drugs. They have no problems with insisting that patients live in appropriately structured and supportive residential settings, to the extent needed by each individual, as a condition for remaining in the community. They are willing to rehospitalize patients in community facilities promptly at times of crisis and are willing to recommend revocation of patients' community status and return them to the court with the opinion that community treatment is no longer appropriate.

It is also important to emphasize the legal and ethical aspects of treating persons under the jurisdiction of the court. Before persons in AOT and offenders with mental illness are asked to consent to outpatient treatment, they should be apprised of all the conditions and limitations that will be imposed on them, why they will be imposed, and what will happen if they do not comply. Areas to be addressed include limits to confidentiality, with respect to both past and present treatment and criminal history, and conditions under which such information must be shared with criminal justice and mental health system personnel; supervision and monitoring by various authority figures, such as probation or parole officers, judges, therapists, and case managers; mandatory adherence with treatment and other imposed conditions; and residence in an appropriate living situation. The patient must understand that nonadherence to the terms and conditions may result in revocation of outpatient status. It is also imperative that the treatment staff understand the patient's legal status and conditions for community placement fully and agree to monitor and uphold them. Staff members must accept their role as agents of social control.

Treatment Goals

Generally, mental health professionals believe that community treatment of persons with serious mental illness who are in AOT and/or have been offenders should focus on stabilization of the illness, enhancement of independent functioning, and maintenance of internal and external controls that prevent patients from acting violently and committing offenses. It is hoped that patients will share these goals. Patients should at least have the goal of avoiding involvement with the criminal justice system. Important points for discussions between the clinician and the patient are the patient's understanding of which behaviors and symptoms are of concern, why they are of concern, what is expected of the patient both by the clinician and by the supervising court or criminal justice agency, and how the treatment can help the patient to meet these expectations.

Even patients with severe psychiatric symptoms may be able to understand these elements of treatment and adopt appropriate attitudes toward treatment. Thus, a full resolution of symptoms is not always needed for treatment to be viable in a community setting. For some persons with long-term, serious mental illness, total elimination of symptoms is not a realistic goal. Rather, the primary prerequisite for safe and effective community treatment may be patients' ability to understand and accept their clinical needs and the system's legal requirements and to demonstrate adherence.

Liaison Between Treatment Staff and the Court

Intense supervision and monitored treatment increase successful outcomes. Therefore, an essential aspect of the treatment of offenders with mental illness, especially those under the jurisdiction of the criminal justice system and of persons in AOT, is a close liaison among treatment staff and the court, the district attorney's office, the departments of probation and parole, and the patient's counsel. At the core of the liaison is a complete and relevant database, which is fundamental in understanding the extent of the patient's problems, determining whether outpatient treatment is appropriate for the patient, and developing a treatment plan. The database should include arrest reports, computerized criminal histories ("rap sheets"), hospital records, evaluations by court-appointed psychiatrists or psychologists, results of psychological testing, probation reports, and records from previous hospitalizations, outpatient treatment, and incarcerations.

A successful liaison requires open, frequent, and continuing contact between the treatment staff and the various aforementioned personnel in the legal system. In addition, all must respect each other's perspectives and accept that they are all working toward the same goals. Together, the mental health and legal systems lend their expertise to developing and modifying the most effective community treatment program for patients. Both must accept that such a program cannot be effective for certain individuals who need hospitalization or are too dangerous and thus are not appropriate for outpatient treatment.

The Need for Structure

Usually, patients referred for mandatory outpatient treatment lack internal controls; they need external controls and structure to organize them to cope with life's demands. For instance, mental health professionals who treat this population generally believe that staff should insist that patients' days be structured through meaningful, therapeutic activities such as work, day treatment, and various forms of social therapy. Another basic element of structure for this population is that treatment is mandatory and under the jurisdiction of the court.

What effect does involuntary treatment have on persons with serious mental illness? Adherence has been shown to increase when persons with serious mental illness are required to undergo involuntary treatment. Adherence is important because it has been demonstrated that persons with serious mental illness who do not comply with treatment present an increased risk to themselves and to the community. Thus, treatment nonadherence may in and of itself result in rehospitalization or incarceration.

For offenders with mental illness, the criminal justice system tends to view outpatient treatment or conditional release programs as provisional; such programs are not regarded as the right of the offender with mental illness. Thus, the courts are not obliged to grant this form of treatment; if granted, the courts allow the state to quickly and easily revoke it. The possibility of revocation of outpatient status gives the treatment staff powerful leverage to ensure adherence to the treatment conditions.

Finally, it is essential that staff understand and accept the therapeutic value of structure and their use of authority if community treatment of offenders with serious mental illness is to be successful.

Management of Violence

A major focus of therapy should be on high-priority issues, such as the need for the patient to control impulses and inappropriate expressions of anger. Persons whose violence is rooted in a major mental illness often experience their violence as a frightening loss of control. Because their violent acts often occur in the context of psychosis, they tend to perceive a clinician who is not aware of their destructive potential as unable to protect them. They tend to establish that knowledge by testing the clinician for limits. The clinician must be continuously alert and firm in order not to risk being perceived as uncaring and unable to protect the patient from their destructiveness. Treatment contracts made by the psychiatrist and the patient that deal with expectations and consequences openly and from the beginning provide a helpful structure for working with these potentially violent patients.

Persons with serious mental illness, especially those with histories of violent behavior, generally need continuous rather than episodic care. Thus, regular monitoring is needed, especially when symptoms are absent or at a low ebb, in order to deal with individual and situational factors that may arise and result in violence.

Persons with serious mental illness who have been hospitalized or incarcerated frequently enter outpatient treatment while they are still taking medication and may, for the first time in years, find themselves symptom-free, in control of their violent impulses, and able to function in the community. After a while, they may believe that they can succeed without medication; they discontinue its use, decompensate, and perhaps engage in violent behavior. Thus, for this population of persons with serious mental illness, many of whom have problems involving control and violence, the importance of continued adherence to antipsychotic medications and medications for bipolar and depressive disorders cannot be overemphasized.

In addition, behavioral, cognitive, and psychoeducational techniques emphasizing anger management have been widely used and are successful in the treatment and management of violence.

Integrating Treatment and Case Management

The purpose of case management is to help patients obtain the services they need in a timely manner and for as long as they need them. Almost all of these patients need the basic elements of case management, which starts with the premise that each patient has a designated professional with overall responsibility for their care.

The case manager formulates an individualized treatment and rehabilitation plan with the patient’s participation. As care progresses, the case manager monitors the patient to determine whether they are receiving treatment, have an appropriate living situation, have adequate funds, and have access to vocational rehabilitation. The treatment plan emphasizes helping the patient to deal with practical problems of daily living. In addition, the case manager provides outreach services to the patient wherever they are living, whether alone, with family, in a board-and-care home, or in another residential setting.

Outreach services may take the form of assertive case management. An assertive case management program deals with patients on a frequent and long-term basis. It takes a hands-on approach that may necessitate meeting with patients on “their own turf” or even seeing a patient daily. This form of contact and familiarity with the patient helps the case manager anticipate and prevent significant decompensation. Low caseloads for case managers of potentially violent persons with mental illness—probably not more than ten cases—have been recommended, as have 24-hour-a-day, 7-day-a-week availability. Many violent acts and arrests occur during evenings, nights, and weekends, when traditional treatment programs are closed.

Patients who perceive the case manager as mainly an agent of the court and whose primary intention is to make them “toe the line” will be less likely to form a positive relationship with a case manager. They may be guarded and defensive in their interactions. They may also feel a need to portray themselves in a good light, even though they have problems for which they need help. Therefore, case managers, in addition to enforcing the terms and conditions of the court and the treatment, need to be persons who will go beyond this role to secure and provide services and support. It is crucial that patients see the case manager as their advocate to further their treatment and rehabilitation, particularly when agencies in the criminal justice system are dealing simultaneously with them in more coercive or authoritarian ways.

Case managers may experience considerable stress in working with patients in mandatory outpatient treatment. They may feel, with some justification, that they are in danger if they work with persons with serious mental illness who were violent in the past or if their work requires visits to high-crime areas, where many persons with serious mental illness live. Additional problems may include unusual working hours, which may disrupt their family and social relationships, and lack of upward career mobility.

Therapeutic Living Arrangements

Survival in the community for most persons with serious mental illness appears to depend on an appropriately supportive and structured living arrangement. Such an arrangement can often be provided by family members. In many cases, however, the kind and degree of structure the patient needs can be found only in a living arrangement outside of the family home with a high staff–patient ratio, dispensing of medication by staff, enforcement of curfews, and therapeutic activities that structure most of the patient’s day.

Some patients need a great deal of structure and supervision in their housing situation. Others need only a minimal amount, and most fall somewhere in between. The treatment staff member assigned to the patient or the patient’s case manager must decide whether a particular living arrangement has the appropriate amount of structure to meet the patient’s needs. However, it is important to first discuss the suggested living arrangement with the court or the responsible agent in the criminal justice system and obtain their approval.

A consideration for all patients who move from a closed or locked setting such as a hospital, jail, or prison is the patient’s ability to handle the transition. It is generally not advisable for persons who have been hospitalized or incarcerated for a long time to then be placed in the community in a living situation with little or no structure. Such individuals are frequently unable to cope with the immediate stress and demands of these arrangements, and they either decompensate or commit subsequent offenses.

For many persons with serious mental illness, it is helpful to release them to graduated lower levels of structure—for example, from a hospital or prison to a locked community facility to a halfway house and, when they are ready, to family or independent living. In the graduated release process, close attention must be paid to patients' coping skills and the need for monitoring.

Working With the Family

The role of family members or significant others can be critical in the treatment of offenders with mental illness or for those in AOT. The treatment team should determine whether these individuals were the victims of the patient's aggression, whether they have maintained contact with the patient, and whether they are interested in continuing such contact. The team should also learn whether other social support systems are available while the patient resides in the community. Social support can be an extremely important part of community treatment for persons with mental illness. Assessing problems that may develop between the patient and family members or significant others is essential if contact between them is anticipated.

Another important consideration is the family members' need for guidance and support, especially when they have been victimized by the patient. Clinicians should help them understand the patient's mental condition, teach them to recognize symptoms of decompensation, demonstrate methods for self-protection, and explain the patient's current legal situation.

Moreover, family members should be involved in support groups to help them during crises. In self-help programs, they can benefit from the experience of other families in similar situations.

Diversity, Awareness, and Sensitivity

It is essential that mental health professionals understand how the roles of ethnicity, race, culture, gender, religion, sexual orientation, and age can affect one's mental health. Equally important is an understanding of the kinds of treatment and how treatment is presented that will be acceptable to these groups. Only then can the mental health system provide to racial, cultural, religious, and ethnic minorities as well as persons of all ages, sexual orientations, and genders services that are appropriate for their needs and ones to which they will be responsive.

Pitfalls

Mental health professionals must understand their potential liability for the actions of their patients on community status who are prone to violence. They need to be aware that in some states, courts have imposed on therapists a duty of care that extends to the foreseeability of harm. Moreover, the litigious nature of society adds further pressures, stress, and risks. Treating clinicians may be held accountable for patients' suicides, assaults, homicides, and other crimes, even when treatment was mandated, sound, and met the professional community's standards of care. In both public agencies and private practice, malpractice insurance coverage must be adequate so that clinicians feel comfortable, personally and professionally, in undertaking the treatment of persons with serious mental illness who need mandatory outpatient treatment.

Another important concern of those clinicians involved in the community treatment of offenders with serious mental illness, especially persons who have committed high-profile crimes, is the possibility of notoriety and unfavorable publicity. Clinicians may fear that if patients commit further sensational crimes, their professional reputation will suffer, and their facility may receive negative media coverage.

Twenty-Four–Hour Structured Inpatient Care

Not all persons with mental illness can be treated effectively in the community. There is a substantial minority of persons with serious mental illness who need the structure and support of acute, intermediate, or long-term care in a hospital setting or a highly structured, locked 24-hour care community facility. It is important to identify high-risk patients so that scarce community treatment resources are used for those most likely to succeed and for those who are least likely to incur the high costs of lengthy hospitalization or rearrest for serious offenses.

It is essential to facilitate access to hospital care for patients who need it. In the early years of deinstitutionalization, many believed that if the counter-therapeutic practices that were exposed in some state psychiatric hospitals could be eliminated, this would simultaneously eliminate the need for hospitals altogether. However, experience has shown that some persons with serious mental illness require hospitalization, and some may need it for an extended period. This may be true even in communities that offer a complete array of excellent and integrated community-based services.

It is important to acknowledge that the community is not necessarily the most benign treatment site for all people with mental illness at all times. Access to hospital care for those who need it for as long as they need it is absolutely essential to the success of deinstitutionalization and the reduction in criminalization for this population.

For those persons with serious mental illness who do not require a setting as highly structured as that of a locked psychiatric hospital but who are not ready for an open community setting, intermediate care facilities have proven extremely valuable. An example is the Institutes for Mental Disease (IMDs) in California. IMDs are locked, private, community intermediate care facilities with a moderate but lesser degree of structure than that found in long-term psychiatric hospitals, such as state hospitals. The facility provides very close medication supervision, with many patients receiving their medication in either liquid or crushed form. The staff–patient ratio is high, with at least 27 hours of activities a week for each patient. These activities include group therapies, therapeutic, social, and recreational activities, and instruction in activities of daily living.

Intermediate care facilities have been used widely for both civil and criminally committed patients. These intermediate care facilities have helped to stabilize persons who might well have been criminalized; for those persons coming from jails and prisons, they might well have prevented recidivism.

Decarceration of Jails and Prisons

Imprisonment rates in the United States increased 500% over the past 40 years, with a peak occurring between 2006 and 2008. Currently, the United States has the highest rate of incarceration in the world. This resulted in prison overcrowding and great financial costs. Consequently, many efforts are underway currently to decrease the number of persons imprisoned. Some of these are reductions in state and federal sentences for less serious crimes, including drug offenses, the use of alternatives to prison by means of diversion programs, offering early release to prisoners who participate in rehabilitation programs, and legal mandates to reduce prison overcrowding.

Beginning in 2009, the number of prisoners in U.S. prisons and jails slightly dropped each year. The greatest reduction in prisoners was in California, which exemplifies many of the factors that led to decarceration. In the case of *Brown v. Plata*, the U.S. Supreme Court in 2011 found that overcrowding in California's prisons resulted in a violation of prisoners' constitutional rights and upheld an order to significantly reduce the number of state prisoners. Legislation known as "Public Safety Realignment" was enacted that year which used two primary methods to reduce overcrowding, costs, and recidivism. The first method focused on reducing admissions to prison by having many nonserious, nonsex, and nonviolent felony offenders serve sentences, generally of 3 years or less, in county jail instead of prison. The second method focused on having fewer prisoners return to prison; that is, inmates who previously were released on state parole were now released under county probation to be supervised and provided services by county agencies. If they violated their conditions of probation (but without committing a new crime), they could not be returned to prison but could be placed in jail.

"Realignment" became effective on October 1, 2011. At that time there were 143,710 state prisoners. By May 26, 2021, the number was 92,503, a reduction of 51,207 state prisoners. Persons with serious mental illness may account for a sizeable number of those released. As mentioned previously, recent studies estimate that approximately 16% of persons in prisons have a serious mental illness. If this percentage holds for the 51,207 reduction in state prisoners, then approximately 8,193 (51,207 × 16%) fewer persons with a serious mental illness are incarcerated in California prisons.

In 2018, California added a new statutory scheme (Sec. 1001.35 to 1001.36 Penal Code) to continue reducing the number of persons with mental illness in the criminal justice system by granting pre-trial diversion for individuals with mental disorders. It is not limited to specialty courts, can apply to individuals arrested for misdemeanors and felonies, offers a variety of care settings, and would result in the expungement of the arrest if successfully completed within the 2-year period of diversion. This form of diversion is for defendants whose mental condition played a significant role in the charged offense, who would respond to mental health treatment, and who would not pose a significant risk of danger to the public if treated in the community. There are codified exclusionary criteria, including certain serious charged crimes (e.g., murder, rape) and diagnoses (antisocial personality disorder, borderline personality disorder, and pedophilia). States across the nation are addressing the financial costs and effectiveness of incarceration for those currently in prison. Relying on local jails instead of prisons to incarcerate offenders is also likely to result in high costs and overcrowding conditions in the jails and lead to releasing the least dangerous jail inmates for more serious offenders. As a result, arresting persons with serious mental illness who commit or are alleged to commit nonserious, nonsex, and nonviolent crimes and placing them in jails may become less common than in the past.

Consequently, the era of the criminalization of large numbers of persons with serious mental illness may be ebbing in both state prisons and jails. The criminal justice system will not be able to absorb the great numbers that it did formerly. As a result, during decarceration, the mental health system may be expected to assume the care and treatment for far more persons with serious mental illness. Some of these individuals may be among the most difficult and expensive to treat, as well as at great risk of decompensation and/or reoffense. If, however, society gives a high priority to successfully treating and reducing the hundreds of thousands of persons with serious mental illness who are currently in jails and prisons, or who are being released, or who are at risk of being arrested, some similar problems encountered during deinstitutionalization may be avoided.

Some Possible Strategies

The list of problems is formidable, but they can be resolved. There would need to be a very large increase in the number of community mental health services, including ACT and FACT teams and intensive case management; co-occurring disorder programs; administration of antipsychotic medications and mood stabilizers (especially important in reducing arrests for those who have problems involving control and violence); crisis response teams; appropriately structured and supportive housing; vocational rehabilitation; social rehabilitation; availability of acute care in the community; access to acute, intermediate, and long-term inpatient care when needed; more flexible civil commitment laws; and

AOT when indicated. Many of these interventions are evidence-based practices. With a sufficient amount of all these services being made available, the number of persons with serious mental illness being criminalized should drop significantly.

With the large numbers of persons with serious mental illness who first come to the attention of law enforcement officers, the opportunity to enter the mental health system should be given to those who are appropriate for diversion. Toward this end, there needs to be many more mobile crisis teams, such as CITs of specially trained police officers, who can find alternatives other than arrest and incarceration for such persons in crisis. There should also be increased education and training on mental illness and available mental health resources for law enforcement officers in general. Diversion after arrest may be accomplished in mental health courts (or even general courts), where persons with mental illness are sent to the mental health system to obtain treatment in lieu of incarceration. It needs to be emphasized that pre- and postbooking diversion can be effective only if there are adequate and appropriate mental health resources to which persons with serious mental illness can be diverted.

For those persons with serious mental illness who enter and remain under the jurisdiction of the criminal justice system, creating a successful treatment program for them is a difficult task that demands the input and cooperation of correctional and mental health professionals who are knowledgeable and accepting of the tenets of both the criminal justice system and mental health treatment. A close liaison among such varied professionals helps to maximize a successful outcome for offenders with mental illness. These persons should be provided with appropriate treatment while they are incarcerated and after they have been released into the community. Moreover, all such programs should be evaluated independently to determine which are effective and which are not to ensure the best possible use of scarce resources.

Finally, a significant increase in mental health services, ranging from outpatient treatment and case management to highly structured 24-hour care, would no doubt result in far fewer persons with serious mental illness committing criminal offenses. There is an enormous stigma attached to people who have been in jails and prisons or in a forensic hospital. Such persons have been categorized as both mentally ill and as offenders, which makes it extremely difficult to place them in community treatment and housing.

In this time of decarceration, psychiatrists are poised to provide persons with serious mental illness the mental health treatment and supportive social services that were inadequately provided previously for so many and thus led to their decompensation and criminal behavior. If the goals of reducing the criminalization of persons with serious mental illness are to be accomplished, the mental health and criminal justice systems must not only work collaboratively to problem solve but also be provided with all the necessary resources and funding to identify and treat these individuals in the most appropriate setting. It cannot be emphasized enough that the criminal justice system should not be used as a substitute for the mental health system.

Psychiatric Education

57.1 Graduate Psychiatric Education

George Alan Keepers, M.D.

Over the last 100 years, the education of physicians in the specialties of medicine has evolved from informal, unsystematized training of variable length and content into the highly regulated residency training programs that constitute the normal educational path for medical school students throughout the United States today. At times gradual, the development of these programs was changed dramatically by the influence of the Flexner report, which resulted in the standardization of both undergraduate and graduate medical education and the adoption of a residency training model begun at Johns Hopkins University. Today, graduate medical education (GME) is undergoing another disruptive episode of evolution championed by the ACGME, the organization responsible for the accreditation of all residency training programs in the United States. In the past, training programs were standardized around the processes and contents of their clinical and didactic curriculum. The Accreditation Council on Graduate Medical Education's (ACGME) competency movement and its more advanced elaboration, the Milestones Project, seek to use measures of the intermediate and final outcomes of residency training to judge the adequacy of training and of training programs.

This textbook has always covered the subject of psychiatric training, but each author has developed the topic in a somewhat different fashion. In earlier editions, the role of the American Board of Psychiatry and Neurology (ABPN) in influencing training programs was emphasized by Lester Rudy and subsequently by Steven Scheiber. James Eaton, in contrast, emphasized the historical development of the field and the influence of the National Institute of Mental Health (NIMH) in providing funding and direction for the development of high-quality training programs. Most recently, Larry Faulkner reviewed the major organizations that influence psychiatric training programs, provided an overview of the organizational structures that regulate and determine the processes and content of training programs, and addressed issues in psychiatric education that were then relevant.

As Faulkner reviewed in detail, psychiatric educators faced a number of controversial issues in the past. Some of these issues have been resolved, while others continue to be very actively discussed. The interference of service requirements in residency with residents' educational activities has been effectively eliminated by ACGME regulations which limit work hours, require protected time for education and incorporate residents' judgments regarding this issue into the ACGME Psychiatry Residency Review Committee's (PRRC) evaluation of training programs. However, certain new problems have arisen as a result of these regulations. Work compression, which is the pressure to accomplish all patient care activities within a limited time, has created new stressors for residents. Some fear that these pressures result in the loss of adequate training experiences since residents can no longer thoroughly evaluate patients or observe the full course of their illnesses.

Conflict in the training curriculum between biologic psychiatry and psychotherapy education has been reduced by the field's consensus regarding the importance of both and by the specification in the PRRC's Program Requirements (PRs) and residency training milestones (discussed below) of specific training requirements in both areas. The conflict between resident support and resident evaluation has also been softened by recent developments. Academic medical centers are increasingly developing resident support systems that exist outside of departmental structures. The movement toward competency-based education embodied in the milestones supports a developmental rather than summative or judgmental approach to residency training.

Nonetheless, balancing the provision of specific feedback based on high expectations while maintaining a positive, nurturing environment for residents remains a challenge.

While ABPN certification following residency remains nominally voluntary, two developments in the field have pressured residents and programs toward 100% participation in certification. First, many, if not most, health systems are now requiring American Board of Medical Specialties (ABMS) specialty certification as a condition of credentialing. Second, the PRRC's PRs, which took effect in July of 2019, require that programs maintain an aggregate 3-year pass rate above the bottom fifth percentile of programs in that specialty.

One issue raised in the previous edition remains a significant area of controversy. The limitation of duty hours and reduction in the clinical responsibilities assigned to residents has had the unintended consequence of reducing residents' continuous contact with patients and delaying their maturation as independent practitioners. It is even uncertain as to whether the reductions in work hours have led to the intended improvements in patient safety, perhaps because of the multiplication in transitions of care required in the new paradigm. It is clear that extended shifts of greater than 16 hours have a negative effect on attentional processes and reaction time. But, thus far, studies have not demonstrated increased patient mortality or morbidity from extended resident duty hours. The ACGME and others continue to study this issue.

This chapter adopts a historical approach to the topic of Graduate Psychiatric Education (GPE). The history of psychiatric training will be described, the development of the organizations responsible for regulating it will be reviewed, and the content and structure of residency training as it now exists will be described. Several recent changes in the conduct of GPE will be discussed, and the above and other controversial topics reviewed.

HISTORY OF PSYCHIATRIC EDUCATION

Early History

Prior to Abraham Flexner's 1910 report for the Carnegie Foundation, medical education in the United States was in an abysmal state. There were no established standards for undergraduate medical education, no requirements for GME, and little to no regulation of the practice of medicine. Different medical traditions, including allopathy, osteopathy, and naturopathy, provided highly varied training experiences. Physicians might then go directly into practice or seek employment, sometimes under the guidance of a more senior physician who had a particular interest. It was not unusual for physicians to practice in fields for which they had no particular training and for their interests and practice to shift during the course of their careers. Those engaged in what is now called psychiatric practice in the United States fell into two camps—on the one hand, the alienists, and on the other, the physicians who conducted ambulatory practices in nervous conditions. These divisions were not original to the United States but were rooted in developments in the field in Europe. The "spa physicians" made great efforts to assert that their clients and practices were different from the mentally ill. The "alienists" explicitly dealt with severely ill patients and were involved, often as superintendents, with newly developed institutions, frequently state-sponsored, which specialized in the care of severely mentally ill individuals. Originally innovative and providing access to moral treatment, these institutions became so overcrowded that they were at best able to provide custodial care.

Many physicians of varying interests practiced and trained in these settings. For example, Dr. James Hawthorne, who established such an institution in Portland, Oregon, was typical of the physicians of this era. A native of Pennsylvania, he began his study of medicine under the tutelage of a local physician Dr. Bascom, later obtaining a medical degree from the Medical University in Louisville, Kentucky. He opened a general practice in Louisville, which became very successful, and repeated this success in California, starting in 1850. He moved to Portland in 1857, opened a general practice, and subsequently established the Oregon Hospital for the Insane. The Hawthorne hospital eventually had 450 psychiatric beds and was supported on the basis of a contract with the state legislature. It was regarded as one of the finest such institutions in the United States, and Dr. Hawthorne, who had no formal training in psychiatry, was known as an expert in the illnesses of the mind. He was a member of the Association of Medical Superintendents of American Institutions for the Insane (organized in 1844), which became the American Psychiatric Association in 1921. Many physicians practiced at the Hawthorne hospital. Most notably, Simeon Josephi came to the hospital and worked under Dr. Hawthorne's supervision. Dr. Josephi left his employment at the hospital to found the Oregon Medical School in 1863. This type of fluid arrangement for training and practice was typical of the times.

Influence of the Flexner Report

Unfortunately, but not surprisingly, this unregulated system led to the public being subjected to poorly trained physicians, naturopaths, and snake oil salesman, all claiming to be legitimate medical practitioners. The American Medical Association (AMA) was organized in 1847 originally to deal with the lack of regulations and standards in medical education and medical practice. Despite the establishment of residency training programs at Johns Hopkins University in 1889, progress was quite limited until the Carnegie Foundation employed Abraham Flexner to study the condition of medical education in the early 1900s. The current system of undergraduate and graduate medical training was founded on Flexner's 1910 report.

Governmental and professional regulatory mechanisms soon followed and have proliferated into a complex group of organizations affecting GPE today. This resulted in the closure of inadequate schools and established allopathy and osteopathy as the only legitimate basis for medical training. Flexner strongly favored the residency program established by Johns Hopkins, and this became and has remained the framework for all residency training in the United States (Table 57.1–1).

Table 57.1–1.
Major Organizations Affecting Graduate Medical Education

American Association of Directors of Psychiatric Residency Training Program	AADPRT	Promotion of excellence in psychiatric training; resources for program directors; provides input to ACGME and ABPN from the field
Association of American Medical Colleges	AAMC	Association medical schools, teaching hospitals, and academic medical centers promoting the improvement of health through enhancing the effectiveness of academic medicine
American Board of Medical Specialties	ABMS	Improvement of health care through setting professional standards for lifelong certification in partnership with the specialty boards
American Board of Psychiatry and Neurology	ABPN	Certification, lifelong learning, and maintenance of certification of psychiatrists and neurologists
American College of Psychiatrists	ACP	Honorary society; develops Psychiatry Resident-in-Training Examination (PRITE) and the Psychiatrist-in-Practice Examination (PIPE) and grants awards to outstanding residents, training programs, and scholars
Accreditation Council of	ACCME	Approval of continuing

Continuing Medical Education		medical education (CME) programs
Accreditation Council for Graduate Medical Education	ACGME	Development of residency training Program Requirements (PRs), Milestones, accreditation of institutions and residency training programs
American Medical Association	AMA	Largest professional medical association. Advocacy for patients and the profession
American Osteopathic Association	AOA	Accreditation of osteopathic schools
American Psychiatric Association (and subsidiary state associations)	APA	Professional association for psychiatrists. Provides multiple education efforts for students, residents, and practitioners. Advocacy for patients and the profession
Educational Commission for Foreign Medical Graduates	ECFMG	Credentialing of international medical graduates for training in the United States
Federation of State Medical Boards	FSMB	Coordinates activities of state licensing boards
Liaison Committee on Medical Education	LCME	Accreditation of Medical Schools
National Board of Medical Examiners	NBME	U.S. National Medical Licensure Exam (USMLE) for medical students and residents
National Residency	NRMP	Regulates recruitment

Matching Program	activities. Matches residents and programs

Following the Flexner report, several specialties (Ophthalmology, 1916; Otolaryngology, 1924; Obstetrics and Gynecology, 1930; Dermatology and Syphilology, 1932) established boards for the purpose of describing training in the specialty and examining candidates for certification. The ABPN was established in 1934 as a collaborative effort of the APA, the American Neurological Association (ANA), and the AMA. Originally, like other Boards, the ABPN both accredited training programs and certified practitioners.

Establishment of the Accreditation Council on Graduate Medical Education

The burden imposed on the Boards by the accreditation of training programs was substantial, and in 1940 the AMA Council on Medical Education, the American Board of Internal Medicine, and the American College of Physicians established the Conference Committee on Graduate Training in Internal Medicine, a forerunner of the ACGME Residency Review Committees (RRCs). The American College of Surgeons and the American Board of Surgery established their own accreditation bodies in 1949.

Academic educators soon realized that, with the establishment of Medicare and federal funding for residency training, the several accrediting organizations then in existence with widely varying standards for approval of training programs were not tenable and required reform. The case for uniformity of standards with a national scope was supported by the AMA, other medical groups, and the government. In 1972, the AMA sponsored the ABMS, the AHA, the AAMC, and the Council of Medical Specialty Societies (CMSS) to form a Liaison Committee for Graduate Medical Education (LCGME) to coordinate the activities of the independent RRCs then in existence. The failure of this effort indicated that an independent, self-sustaining organization was required to accomplish these tasks, and the ACGME replaced the LCGME in 1981. The ACGME was charged with the responsibility for the accreditation and monitoring of residency programs throughout the United States. In the subsequent years, the current system of RRCs, PRs, and periodic accreditation site visits was developed.

The evolution of the ACGME PRs in psychiatry has been a collaborative effort between the ACGME, the ACGME PRRC, psychiatric professional organizations, and the ABPN. This has resulted in more uniform, higher-quality training throughout the United States and an alignment between completion of an accredited residency and eligibility to take the ABPN certification examination. Beginning in 2010, the ACGME undertook a major revision of the methods used to evaluate residents and training programs. Entitled the Next Accreditation System (NAS), this new system exchanges yearly reviews of data from all programs with the selection of outliers for review for the old system of in-depth reviews of all programs every 5 years following site visits. The details of this system are discussed below.

The American Board of Psychiatry and Neurology

The ABPN retained the task of certifying graduates of accredited training programs in psychiatry and neurology. The ABPN, like the other 24 specialty boards of the ABMS, is a nongovernmental, independent, nonprofit 501(c) 3 organization governed by a board of directors (Table 57.1–2).

The board is comprised of eight psychiatry directors and eight neurology directors, each of whom serves two 4-year terms (Table 57.1–3). Currently, the Board includes nine neurology directors due to a unique circumstance. Candidates for selection as psychiatry directors are solicited from the APA, the American College of Psychiatry (ACP), and the AMA. The ANA and the American Academy of Neurology (AAN) nominate candidates in neurology. Current directors of the board may also nominate candidates.

Certification methods have changed through the years, and these changes are detailed elsewhere in this text. Two most recent developments are of great importance to psychiatric educators. Ending a 75-year tradition, the last ABPN oral examination in general psychiatry was given in Portland, Oregon, at Oregon Health & Science University in 2015. The oral examination in child psychiatry was discontinued not long afterward, with the last examination conducted at Northwestern in Chicago. The new certification examination in General Psychiatry has proven to have very high reliability, with passage rates that are similar to those of the old Part I examination (Table 57.1–4).

2022	1,966	1,752 (89)

Data from American Board of Psychiatry and Neurology (ABPN). Initial Certification Statistics report. Available at: https://www.abpn.org.

Going forward, all of the ABPN's examinations in the core specialties of psychiatry, child psychiatry, and neurology, as well as the subspecialties, will be single certification examinations conducted at testing centers throughout the United States. Psychiatric residency training programs must certify the credentials of their graduates through the computerized ABPN PreCert system as a condition of eligibility to take the examination. Data from this system make it feasible to accurately ascertain the quality of residency training programs as measured by certification examination passage rates for individual programs.

Also of interest is the ABPN's return to a role in the accreditation of residency training programs. The ABPN collaborates with other ABMS boards to develop a number of combined educational programs that are not ACGME accredited. The core programs contributing to the training are ACGME accredited programs, but the training track for residents in the two programs is not. Residents complete training in these programs in less time than it would take to complete the specialty training programs separately. These programs include training that leads to certification in psychiatry and neurology, psychiatry and internal medicine, and psychiatry and family medicine. The Triple Board Program was established as a collaboration between the ABPN and the American Board of Pediatrics (ABP) in 1984. Graduates of these programs may take the certification examinations in psychiatry, child and adolescent psychiatry, and pediatrics.

A small but significant number of institutions offer these combined training programs. These programs cannot be accredited by the ACGME, although the specialty programs which participate in them are reviewed and accredited by their respective RRCs. The ABPN has agreed to provide regular review and approval of the combined training programs in order to assure quality training for the residents in these programs and to assure that graduates will be eligible to take the certification examinations in each specialty (Table 57.1–5).

[a] Multispecialty examination.

Modified from American Board of Psychiatry and Neurology (ABPN). ABPN website history. Available at: https://abpn.org/about/mission-and-history/.

The Subspecialties of Psychiatry. Child and Adolescent Psychiatry was the first subspecialty of psychiatry for which the ABPN developed a credentialing process and certification examination. Subsequently, nine other subspecialties were identified, and the ABPN now certifies subspecialists in these areas (Table 57.1–6).

The ABMS has specific criteria for the establishment of new subspecialties, and approval for their inclusion must be obtained from that organization. All of the subspecialties in psychiatry require completion of an ACGME accredited residency, except Brain Injury Medicine, which is still in the grandfathering period extended to 2022, and Addiction Medicine, with a grandfathering period until 2025. The ACGME PRRC accredits Child and Adolescent, Geriatric, Forensic, Consultation-Liaison (changed from Psychosomatics in 2017), and Addiction residencies. The other residencies are administered by other boards. All of the subspecialties are 1-year fellowships, except for Child and Adolescent Psychiatry, which is a 2-year program. Residents may enter Child and Adolescent Psychiatry during any part of a General Psychiatry program. One year of training may be counted for both programs, enabling the completion of both programs in 5 years rather than 6. A previous discussion in the field was whether to allow completion or partial completion of the other subspecialty fellowships in the fourth year of the general residency. Although the discussion continues, none of the steps that would be required for such a change have been initiated. All of the subspecialty certifications require taking a single computerized certification examination except for Child and Adolescent Psychiatry. That specialty had traditionally had a Part II oral examination, which was eliminated in 2016 after the completion of the last oral examination at Northwestern in Chicago.

Many subspecialties are developed collaboratively between several ABMS boards. Sleep medicine is an example of such a subspecialty. One of the boards will take the lead in administering the subspecialty and developing the certification examination. Each member board is responsible for credentialing candidates from their own specialty. As new subspecialties are recognized by the ABPN and ABMS, a grandfathering period, usually 5 years, is allowed during which candidates who meet established criteria for experience in the subspecialty area may take the certification examination without completing a residency. After this period expires, candidates must complete appropriate residency training programs to be eligible to take the exam. Of particular recent interest is the development of the multidisciplinary subspecialty of Addiction Medicine, which is administered, oddly, by the American Board of Preventative Medicine. There are now more fellowship programs in Addiction Medicine than in Addiction Psychiatry, and many previously uncertified addiction specialists have taken advantage of the grandfathering period to become certified. The Practice Pathway for such individuals will remain open until 2025.

Table 57.1–7.
Psychiatry and Subspecialty Training Programs Numbers and Resident Census 2015–2020

		2015–16	2016–17	2017–18	2018–19	2019–20

Modified with permission from Accreditation Council for Graduate Medical Education (ACGME). Data Resource Book Academic Year 2019–2020. Available at: https://www.acgme.org.

The number of core psychiatry subspecialty programs and subspecialty fellows has not kept pace with the increase in the numbers of general programs and residents. Except for Child and Adolescent Psychiatry, these programs have fewer than 90 fellows in training each year. This is problematic from the standpoint of providing an adequate workforce, particularly in geriatric and addiction psychiatry. The failure to interest sufficient numbers of residents in subspecialty fellowship training is the subject of considerable discussion and distress for the profession (Table 57.1–7).

The American Board of Medical Specialties

In 1933, the American Hospital Association (AHA), the Association of American Medical Colleges (AAMC), the Federation of State Medical Boards (FSMB), the AMA, the National Board of Medical Examiners (NBME), and representatives of the four specialty boards in existence at that time (Ophthalmic Examinations, Otolaryngology, Obstetrics and Gynecology, and Dermatology and Syphilology), established the Advisory Board for Medical Specialties. Originally the ABMS was to serve as an advisor to the Boards, a forum for discussion of common problems, and a coordinator of board work when feasible. When expressly delegated by the Boards, the ABMS was to assume control over common policies and procedures. The organization was restructured in 1970 into the ABMS. The AHA, AAMC, FSMB, AMA, and NBME, along with the CMSS, the ACGME, and the Educational Commission for Foreign Medical Graduates

(ECFMG), continue to serve as associate members of the ABMS. The ABMS derives its funding through levies on the Specialty Boards and, in recent years, has assumed a more directive role with its 24 member Boards. In particular, the ABMS has established standards that the boards are required to follow, specifying what steps diplomats of the boards must take in order to maintain their certification. The ABMS has proposed a revision to these standards that emphasize quality improvement in health care and professionalism. The proposed ABMS requirement that the Boards assess professionalism in their diplomats is controversial for practical and legal reasons.

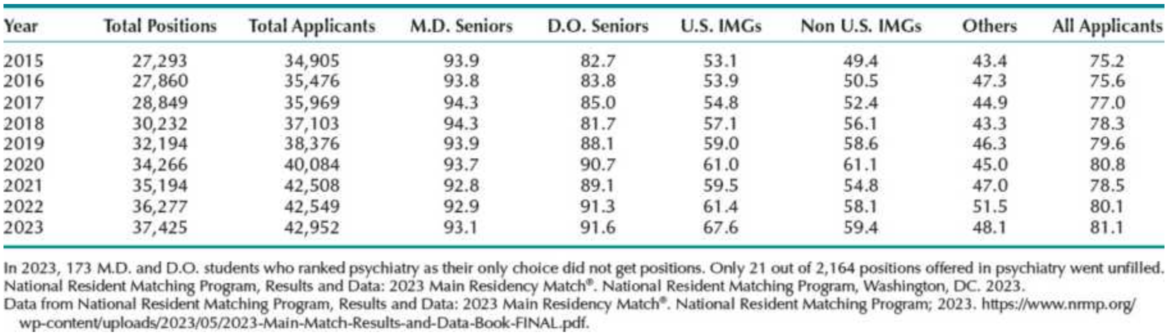
These Maintenance of Certification (MOC) or Life Long Learning programs currently consist of four elements: professional standing (medical licensure), continuing medical education (CME), self-assessment (SA), and performance in practice (PIP), which includes patient and peer feedback and systematic evaluation of the diplomat's clinical care. Additionally, all diplomats of the boards must document the completion of a patient safety course.

In conjunction with the ACGME, the ABMS and some member boards have begun to offer U.S. training standards for residencies and practitioner certification abroad. Singapore was the first country to request this program and now has a robust program of residency training and certification for several specialties that is similar to the U.S. equivalents. ACGME international programs are now training residents in China, Guatemala, Haiti, Kenya, Lebanon, Oman, Pakistan, Qatar, Saudi Arabia, and the United Arab Emirates, in addition to Singapore. ABMS International has helped to develop certification in examinations in 12 specialties in Singapore, including a certification examination in Psychiatry.

The Liaison Committee on Medical Education

Interestingly, accreditation processes for undergraduate medical education were unified later than the initial wave of certification for specialists. The Liaison Committee on Medical Education was not founded until 1942. Prior to its founding, the AMA's Council on Medical Education and Hospitals inspected and approved medical schools and approved hospitals for internships. The AAMC approved medical schools for membership in the AAMC. Leaders of the AAMC and the AMA, in an effort to avoid duplication of effort, assure the quality of training, protect medical students from the wartime draft, and counteract pressures to shorten medical training, established the LCME at a meeting in Chicago. The LCME established and has maintained the standard that made psychiatric education and rotations one of the required experiences for all medical students. This standard has been critical to maintaining an appropriate place for psychiatric education in the medical school curriculum when it has been challenged on intellectual and, more recently, economic grounds.

Table 57.1–8.
PGY1 Match Rates



Year	Total Positions	Total Applicants	M.D. Seniors	D.O. Seniors	U.S. IMGs	Non U.S. IMGs	Others	All Applicants

PSYCHIATRIC EDUCATION TODAY

Resident Recruitment and the NRMP Match

Postgraduate psychiatric education today begins with what everyone calls “the Match.” Prior to the establishment of The National Resident Matching Program (NRMP), enrollment in a residency training program depended on individual negotiations between graduating medical students and the training program’s director. Students were often pressured to accept a position in a program immediately, frequently before they had had an opportunity to interview for and consider other programs. The NRMP was established in 1952 in an effort to prevent these abuses and provide a level playing field for all the programs and applicants. The NRMP is governed by a board of directors, with nominees from the ABMS, the AMA, the AAMC, the AHA, the CMSS, the AAMC Organization of Student Representatives, the American Medical Student Association, the AMA Medical Student Section, and the Consortium of Medical Student Organizations.

Each year, the recruitment process, in anticipation of the NRMP match day in March, preoccupies most GPE program directors (PDs), senior medical students, and many current residents who are very interested in the younger colleagues who might join them in their residency program. Selecting and recruiting strong candidates for residency training is a critical task for departments. During the recruitment season in 2020 and 2021, all recruitment interviews were done through virtual means due to the COVID pandemic. It remains to be seen whether this methodology will become a permanent feature in future recruitment years. Successful recruitment benefits the department’s training program, its future faculty, and the communities which depend on the department for the services of its graduates. Ideal candidates, like those described by Johann Christian Reil in 1803, are the subject of intense competition between training programs.

> Perspicacity, a talent for observation, intelligence, good will, persistence, patience, experience, an imposing physique, and a countenance that commands respect. All those qualities required for the cure of the insane are so rare as to make the staffing of institutions difficult.

It is not much of an exaggeration to say that good residents make good teachers and good training programs. Bright, enthusiastic, conscientious residents are rewarding to teach and contribute to a stimulating scholarly environment. Unfortunately, residents who display the opposite characteristics can cast a pall over the entire training program.

The NRMP has specific guidelines that govern the interview and recruitment process for residency applicants, and all GPE programs and medical students must agree to comply with them in order to participate in the NRMP match. The NRMP has established a uniform date of appointment for GME positions and a system for matching medical students and residency training programs that depends on lists that rank program preference (by the applicants) and applicant preference (by the programs). These lists are computer-matched to produce the best possible outcome for both parties. In 2021, almost 27,000 U.S. medical students (M.D. and D.O.) participated in the NRMP match, and almost 22,000 “independent” applicants applied for approximately 38,000 positions in over 4,000 GME programs across the United States. “Independent” applicants include former graduates of U.S. medical schools, U.S. osteopathic students, Canadian students, and graduates of international medical schools.

Since 1995, the number of applicants for these positions has substantially exceeded the number of positions. This trend has accelerated over the last 10 years with the inclusion of many more U.S. IMGs and Osteopathic medical students in the Match. This has produced substantial anxiety on the part of today's applicants regarding their likelihood of obtaining a residency position. In fact, the probability of a graduate of a U.S. institution succeeding in the Match has changed little over the last 25 years. About 90% of these graduates will match with a program they have ranked. Other candidates have cause for considerable anxiety. They will succeed in obtaining a position less than 50% of the time. In the last several years, the number of psychiatry training programs and applicants has grown dramatically. Almost all residency training programs in General Psychiatry fill their positions in the match. Recently, many graduates of U.S. medical schools have not been able to obtain a residency position in psychiatry. The proportion of residents from U.S. medical schools is now higher than what is found in Internal Medicine and Family Medicine residency training programs (Tables 57.1–8 and 57.1–9).

Table 57.1–9.
Psychiatry Residency Training Positions, Number of Positions Filled, and Number of Positions Filled by U.S. Graduates 2017–2021

Year	Positions	Positions Filled	Filled by U.S. Graduates
2017	1,495	1,491 (99.7)	923 (61.7)
2018	1,556	1,540 (99.0)	982 (63.1)
2019	1,740	1,720 (98.9)	1,054 (60.6)
2020	1,858	1,838 (98.9)	1,138 (61.2)
2021	1,907	1,904 (99.8)	1,205 (63.2)

Data from National Resident Matching Program, Results and Data: 2023 Main Residency Match®. National Resident Matching Program; 2023, Tables 7A and 7B. https://www.nrmp.org/wp-content/uploads/2023/05/2023-Main-Match-Results-and-Data-Book-FINAL.pdf.

Funding of Residency Positions

The residency positions for which these candidates are competing are funded by a variety of means. The federal government is by far the biggest sponsor of training stipends through two means. First, teaching hospitals receive direct and indirect graduate medical education funding (DME and IME) directly from the Centers for Medicare and Medicaid Services (CMS). These payments are based on a complicated formula that takes into account the percentage of Medicare patients treated at the facility, the historical number of positions when the program was started, and regional cost variations. Many hospitals and universities have many more residents than are approved and funded under the “cap” allowed by this formula, and there are dramatic differences in reimbursement by region. The second mechanism is funds provided by the Veteran’s Administration for residency positions, which in many programs provide a substantial number of stipends. State mental health divisions, community mental health centers, private hospitals, and other organizations also fund some residency positions. All of these organizations expect clinical services in return for the funds they provide. It is often very challenging for a PD to construct a program that satisfies the clinical service demands of the funders and provides the educational program required by the PRs of the ACGME PRRC.

Program Requirements for Psychiatric Training

The ACGME’s process for determining the requirements that programs must meet involves obtaining extensive input from the field, revisions by the RRC followed by more feedback from the field, and subsequent revisions. The ACGME Committee on Requirements reviews the PRs and has the authority to withhold final approval. Increasingly the ACGME has sought to standardize the language and content of the PRs across specialties, so that much of what is found in the psychiatric and psychiatric subspecialty PRs is the same as in other specialties. The PPRs cover the issues of institutional sponsorship and resources, qualifications of the PD and faculty, creation of an academic environment, necessary clinical experiences, mandatory educational curriculum, work conditions, evaluation of residents, evaluation of the program and faculty, and specific outcomes in the language of the ACGME competencies. Recently, the process of evaluating residents has become much more systematic with the development of the milestones (discussed later in this chapter).

Institutional Requirements. Institutions must make a substantial investment in their residency training programs in order to become ACGME-accredited. Institutional accreditation is required before any residency training program can be approved. The institution must appoint a Designated Institutional Official (DIO) who has authority and responsibility for the oversight and administration of the institution's ACGME accredited programs and is ultimately responsible for compliance with the ACGME Institutional, Common, and Specialty PRs. The institution must also establish a Graduate Medical Education Committee (GMEC), which conducts annual program reviews on all residency training programs and, in general, is responsible for the maintenance of a safe and effective learning environment. Many other aspects of institutional investment are mandated, including sections on resident contracts, work environment, learning environment, and responsiveness to ACGME oversight. The ACGME has recently started a new program of institutional review entitled Clinical Learning Environment Review (CLER). The purpose of this review is to assess the GME learning environment of each sponsoring institution and its participating sites. A site visit is conducted during which the site visitors assess the institution through direct observation and interviews of residents and other personnel. This program duplicates much of the work of the Joint Commission on Hospital Accreditation (JCAHO).

The PPRs further elaborate on what is required to conduct a psychiatric residency training program. The subspecialty PPRs are similar and will not be separately covered. The requirements include special provisions addressing the physical facilities which are necessary for psychiatric training. Adequate office space for interviewing patients and equipment for recording sessions with patients are examples of these types of requirements. The types, length, and supervision of clinical experience specific to psychiatry are detailed in the PPRs, as are certain aspects of the ACGME competencies.

The Program Director. The PPRs specify that the residency training PD must be an ABPN-certified psychiatrist with sufficient administrative and educational experience to take on the challenging task of leading the program. The PD is expected to have full authority over the program and to have sufficient tenure in the position to be effective. The core duties of the PD are mandated in the PRs. These include the selection of training sites and the development of program letters of agreement (PLAs) between external sites and the sponsoring institution. The PD must appoint a site coordinator and faculty for each rotation. The PD is responsible for conducting regular evaluations of the rotations and of the faculty and for removing faculty from their teaching roles if necessary. The PD must select residents for the program, evaluate their performance, monitor their stress, and provide twice-yearly formal evaluations. Compliance with ACGME and institutional policies and procedures, particularly those concerning limitations of duty hours and grievance procedures, is required. A summative evaluation at the end of residency training is required, and the resident's rotations and educational experiences must be conveyed to the ABPN at the end of residency to assure eligibility to take the certification examination. The PRRC has, not surprisingly, required that the institution fund and the PD devote at least one-half of their efforts to the training program. Success in this highly technical and demanding position requires at least this much effort.

The Faculty. Psychiatric faculty in an RTP must also be certified by the ABPN, have a strong interest in education, and devote sufficient time to fulfill their supervisory and educational duties. Other teaching physicians should be certified by their specialty board. Non-physician faculty must have completed training, certification, and licensure appropriate to their profession. The maintenance of an academic, scholarly environment is critical to the success of the educational program. All of the faculty should regularly participate in clinical teaching rounds, conferences, grand rounds, journal clubs, and other activities common to the academic setting. Some of the faculty must be engaged in research activities. Demonstration of the faculty's scholarship may be through acquisition of peer-reviewed funding, publication of peer-reviewed articles, other publications, presentations at regional and national meetings, participation in quality assurance activities, and participation and leadership in regional and national professional organizations.

Clinical Experiences. The clinical experiences that psychiatric residents must have during residency are listed in Table 57.1–10. Note that in the first year of residency, the internship must include 4 months of experience in a primary care setting. The purpose and format of the primary care experience are subjects of considerable debate in the field at this time. Currently, most residents complete these experiences in inpatient Internal Medicine wards caring for very ill patients for a brief period of time. These clinical situations are unlikely to be encountered regularly in practice by most psychiatrists. They do, however, have a formative effect on the resident's identity as a physician. Experience in ambulatory or integrated care settings may prove to be more valuable to the psychiatrists of the future. Currently, the PPRs do not require training in the collaborative care environments that many psychiatrists and the APA consider essential to the future delivery of psychiatric care.

Table 57.1–10.
Required Psychiatric Graduate Education Clinical Experiences

Experience	Months Required
Primary Care	4
Neurology	2
Inpatient Psychiatry	6–16
Outpatient Psychiatry	12
Child and Adolescent Psychiatry	2

Community Psychiatry	_[a]
Emergency Psychiatry	_[a]

[a] Required experiences without specific time requirements.

Data from Accreditation Council for Graduate Medical Education (ACGME) Program Requirements for Graduate Education in Psychiatry. Available at: https://www.acgme.org.

Most programs include the required 2 months of experience in neurology in the first year, leaving 6 months which is usually comprised of required psychiatric rotations. Inpatient experiences must include at least 6 months with direct responsibility for the care of acutely ill general psychiatric patients. A wide variety of settings are acceptable for this experience, including traditional inpatient wards, research wards, and specialty care units. The outpatient requirement of a year must include longitudinal treatment of patients with multiple modalities. Some of the resident's patients must be seen weekly under supervision for psychotherapeutic treatment. Forensic, emergency, and community psychiatry experiences are not required to have a minimum duration but must include certain key experiences. For example, in their emergency psychiatry experience, residents must evaluate, manage, and triage acutely ill psychiatric patients. Elective opportunities that enhance and specialize residents' training experiences must be available. These are usually provided in the more senior years of the residency (Table 57.1–10).

A unique aspect of the PPRs is the ability to double-count certain experiences for the completion of both the general and child and adolescent residencies. This enables residents to complete training in general and child psychiatry in only 5 years. One month of child neurology, pediatric consultation, addiction psychiatry, and 20% of the resident's ambulatory psychiatry experience may be double-credited, and the experiences in community and forensic psychiatry can count for both programs. This feature, recognized by the ABPN as a legitimate path to eligibility for board certification, has been important to the successful recruitment of residents into child and adolescent training programs.

Didactic Curriculum. A formal didactic curriculum must be provided for the residents during training. The PD is expected to establish goals and objectives for the curricular components that are couched in terms of the ACGME competencies. These have now been considerably elaborated and are covered in the section below entitled Psychiatric Milestones. The curriculum must be designed in a progressive manner that enables resident progression in their knowledge of the field. It is not acceptable to provide the same seminar material to all years of residents simultaneously. The time for the didactics must be protected from clinical duties so that resident attendance is not compromised. The program must document that residents attend at least 70% of these didactic sessions.

Evaluation of Residents. Due to recent radical changes in the process of program evaluation discussed below, the process of resident evaluation in training programs has drastically changed. The ACGME now requires programs to report on each resident's progress twice yearly. A requirement for a Core Competencies Committee (CCC) has been established. The PD is expected to appoint the CCC, which must consist of at least three faculty members. Residents may not be members of the CCC. The committee must utilize evaluations provided by clinical supervisors and other personnel on rotations, test scores from the PRITE examination, Clinical Skills Examinations (CSEs), and other evaluative methods. The CCC must rate each resident on the milestones semiannually, and these ratings must be reported to the ACGME. These evaluations are developmental in approach and indicate areas of strength and weakness. The resident, PD, and faculty are expected to work collaboratively to improve resident performance in areas of relative weakness.

Summative evaluations at the end of each residency year and at the end of residency must be recorded so that there is a record of the resident's completion of all required rotations and attainment of sufficient competency on the ACGME competencies to enable independent practice and ethical and professional behavior. Uniquely in psychiatric (and neurologic) training, successful completion of clinical examinations, in which the resident interviews a patient while attaining and maintaining rapport, conducts a mental status examination, and presents the data collected in an organized fashion, is required by the ABPN for eligibility to take the board examination. Psychiatry residents must successfully complete at least three such evaluations during residency. This in-residency oral examination was established by the ABPN as a requirement for eligibility to take the certification examination and is in the PPRs. It replaces Part II of the old board examination. The residency program must provide all of this data to the ABPN through the PreCert system to ensure the eligibility of the resident to take the board examination.

The Psychiatry Milestones

In 1999, the ACGME and ABMS, realizing that medical practice required more than medical knowledge and skill in patient care and procedures, established additional competencies which physicians are expected to attain during the course of their training. These competencies should be regarded as desired outcomes that medical training produces. The six Core Competencies are Patient Care, Medical Knowledge, Practice-Based Learning and Improvement, Interpersonal and Communication Skills, Systems-Based Practice, and Professionalism. Requirements for inclusion of training in these areas are included in all of the ACGME PRs and describe behaviors, attributes, or outcomes that must be demonstrated by residents as they advance in training. For example, in the competency of Professionalism: “Residents must demonstrate a commitment to carrying out professional responsibilities and an adherence to ethical principles. Residents are expected to demonstrate: compassion, integrity, and respect for others; responsiveness to patient needs that supersedes self-interest; respect for patient privacy and autonomy; accountability to patients, society and the profession; sensitivity and responsiveness to a diverse patient population, including but not limited to diversity in gender, age, culture, race, religion, disabilities, and sexual orientation; and (specialty-specific outcomes).”

The milestones for residency training represent the next iteration in specifying the outcomes rather than the processes of residency training. Detailed accounts of the development of the ACGME milestones project have been published in the *Journal of Graduate Medical Education* and the *New England Journal of Medicine*. In brief, public and political concern about the outcomes of medical training resulted in a call for reform from the Institute of Medicine (2000), Council on Graduate Medical Education (2007), Josiah Macy Jr. Foundation (2011), and Medicare Payment Advisory Commission (MedPAC) reports (2011). The ACGME response to this crisis in 2008 was to require the creation of milestones describing resident progress in the Core Competencies for all specialties. This project was conceived as a method for evaluation of individual resident progress that would be uniformly applied across the United States and as a method to evaluate the efficacy of residency programs in producing the desired outcomes.

Internal Medicine, Pediatrics, and Surgery were the first specialties to begin milestone development in 2009. In 2011, psychiatry and the other remaining specialties began development with the goal of completing all specialty milestones by 2014. Representatives from the ABPN, APA, American Association of Directors of Psychiatric Residency Training (AADPRT), and ACGME selected individuals to participate in milestone development for psychiatry, and the Working Group and the Advisory Group were formed (Table 57.1–11).

The Working Group was charged with milestone development and began meeting in December of 2011. The Advisory Group reviewed this work and suggested potential improvements. The development of milestones required five meetings and numerous conference calls over the course of the next 2 years. Extensive feedback from the field was sought as part of this process and was incorporated into the final documents. Details of the Psychiatry Milestone development process have been published in Academic Psychiatry. In 2016, the ACGME began the process of revising the milestones due to dissatisfaction with the complexity and inconsistencies in Milestones 1.0. The rationale and processes involved were described in the Journal of Graduate Medical Education. A Milestones 2.0 Group was selected for the revision of the Psychiatry Milestones and developed a set of milestones in which the subcompetencies in System-Based Practice, Problem-Based Learning and Improvement, Professionalism, and Interpersonal Communication were more closely aligned with other specialties. Additionally, the Workgroup developed a Supplemental Guide to assist faculty in assessing resident progress (Table 57.1–12).

Source: Accreditation Council for Graduate Medical Education. Data abstracted from The Psychiatry Milestones 2.0.

The milestones are intended to allow faculty to rate the development of a resident’s skills, ability, knowledge, attitudes, and behavior in achieving the ACGME competencies during training. They are developmental in nature. Basic skills in an area are expected at the beginning of training. Residents are expected to enhance these skills and, by the end of the residency, attain a level of accomplishment that will allow independent practice. The milestones are organized for the purpose of rating resident accomplishments into five levels. Level 1 corresponds to what is expected of a beginning resident. As residents complete their rotations and educational experiences, they are expected to attain Levels 2 and 3 as intermediate stages of accomplishment. It is important to note that the levels in the milestones do not correspond to PGY levels. Residents will progress at different rates within a program, and programs differ in what experiences they offer residents in each year of residency training. By the completion of residency, residents will, on average, have progressed to Level 4 on most milestones. This accomplishment, however, is not sufficient for graduation. The milestones do not measure every quality that is important, and the PD must make an independent judgment on the readiness of the graduating resident for independent practice (Table 57.1–13).

Table 57.1–13.
Description of the ACGME Milestones Levels

Has not achieved Level 1. The resident does not demonstrate the milestones expected of an incoming resident

Level 1. The resident demonstrate milestones expected of an incoming resident

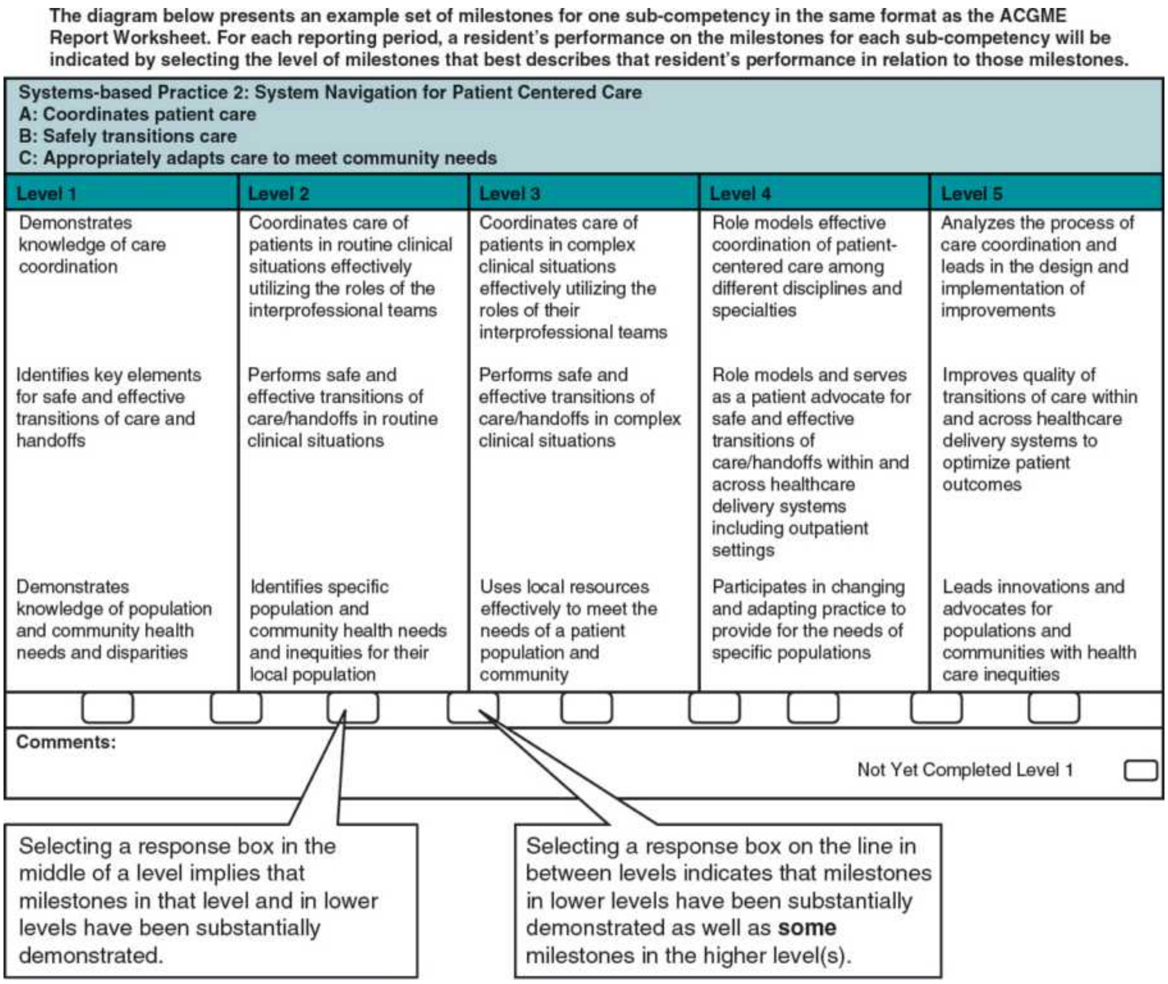
Level 2. The resident is advancing and demonstrates additional milestones but is not yet performing at a mid-residency level

Level 3. The resident continues to advance and demonstrate additional milestones; the resident demonstrates the majority of milestones targeted for residency in this subcompetency.

Level 4. The resident has advanced so that they now substantially demonstrate the milestones targeted for residency. This level is designed as the graduation *target* and does not represent a graduation *requirement.* Making decisions about readiness for graduation is the purview of the residency program director.

Level 5. The resident has advanced beyond performance targets set for residency and is demonstrating “aspirational” goals, which might describe the performance of someone who has been in practice for several years. It is expected that only a few exceptional residents will reach this level.

Accreditation Council for Graduate Medical Education. Data abstracted from discussions in the Psychiatry Milestones Committees.



The diagram below presents an example set of milestones for one sub-competency in the same format as the ACGME Report Worksheet. For each reporting period, a resident's performance on the milestones for each sub-competency will be indicated by selecting the level of milestones that best describes that resident's performance in relation to those milestones.

Systems-based Practice 2: System Navigation for Patient Centered Care
A: Coordinates patient care
B: Safely transitions care
C: Appropriately adapts care to meet community needs

Level 1	Level 2	Level 3	Level 4	Level 5
Demonstrates knowledge of care coordination	Coordinates care of patients in routine clinical situations effectively utilizing the roles of the interprofessional teams	Coordinates care of patients in complex clinical situations effectively utilizing the roles of their interprofessional teams	Role models effective coordination of patient-centered care among different disciplines and specialties	Analyzes the process of care coordination and leads in the design and implementation of improvements
Identifies key elements for safe and effective transitions of care and handoffs	Performs safe and effective transitions of care/handoffs in routine clinical situations	Performs safe and effective transitions of care/handoffs in complex clinical situations	Role models and serves as a patient advocate for safe and effective transitions of care/handoffs within and across healthcare delivery systems including outpatient settings	Improves quality of transitions of care within and across healthcare delivery systems to optimize patient outcomes
Demonstrates knowledge of population and community health needs and disparities	Identifies specific population and community health needs and inequities for their local population	Uses local resources effectively to meet the needs of a patient population and community	Participates in changing and adapting practice to provide for the needs of specific populations	Leads innovations and advocates for populations and communities with health care inequities

Comments:

Not Yet Completed Level 1 ☐

Selecting a response box in the middle of a level implies that milestones in that level and in lower levels have been substantially demonstrated.

Selecting a response box on the line in between levels indicates that milestones in lower levels have been substantially demonstrated as well as **some** milestones in the higher level(s).

FIGURE 57.1–1. An example of milestones subcompetency performance level reporting. (Reprinted with permission from Psychiatry Milestones, 2nd Revision. © 2020 Accreditation Council for Graduate Medical Education (ACGME). Available at: https://www.acgme.org.)

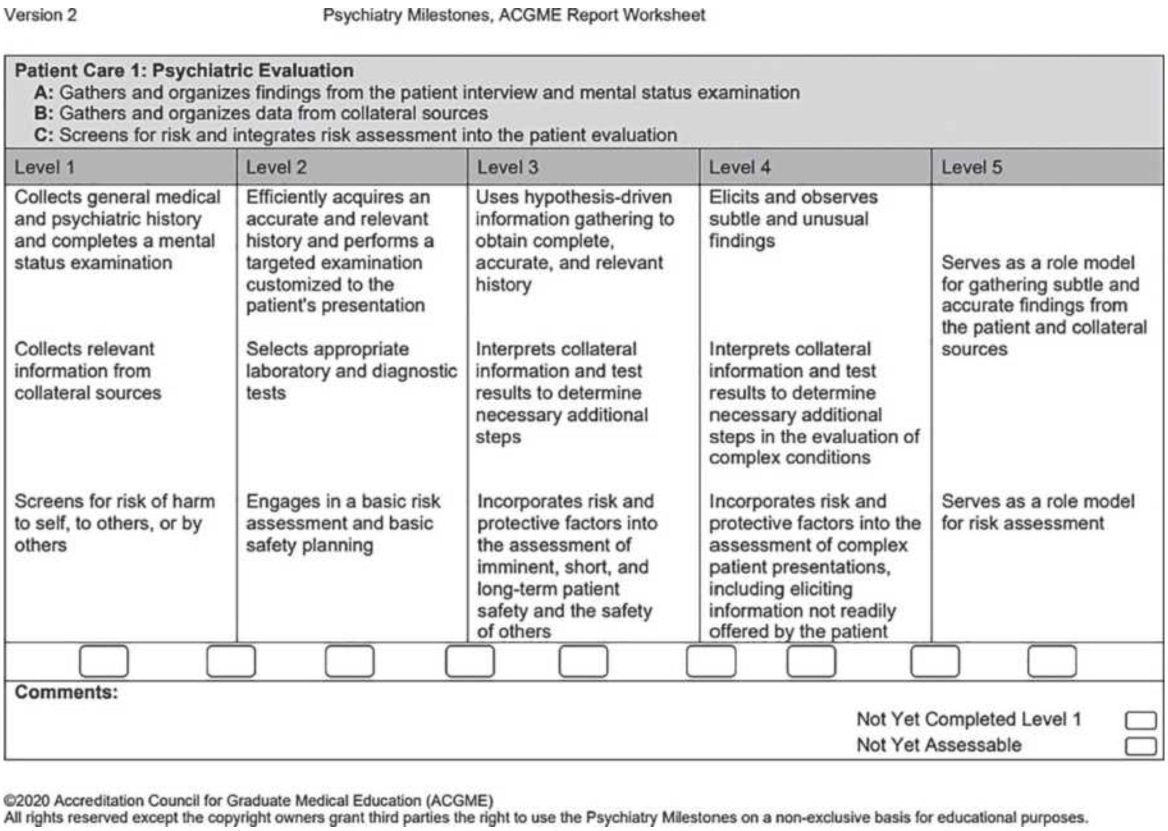
In the milestones, each of the six ACGME competencies contains subcompetencies that describe specialty-specific elements of the general Core Competency. In the Psychiatry Milestones 2.0, there are 20 subcompetencies. There are an additional 32 subheadings in the milestones, which are called “threads.” The Milestones 2.0 revision reduced the number of areas requiring evaluation by 50% (Fig. 57.1–1).

Subcompetencies describe the progression of specific skills, knowledge, or attributes in a single area, such as psychiatric interviewing. The underlying milestones are organized into threads that describe the component skills of the subcompetency and the progression of these skills across the levels (Fig. 57.1–2).

The psychiatry milestones, subcompetencies, and threads are presented in Table 57.1–14.

Milestones for each of the subspecialties of psychiatry were completed after work on the general psychiatry milestones was finished. This work utilized the experience of the original milestone committee members who participated and chaired the subspecialty development committees to rapidly complete this task. A schematic outline of the subspecialty milestones was created to assist the committees in their task. Committee members met for a single face-to-face working session at the ACGME headquarters in Chicago. The Advisory Committee reviewed the work accomplished at the meeting and provided suggestions. The Working Group subsequently accomplished the revisions through conference calls and online participation. Subspecialty milestones are currently being revised (Table 57.1–15).

The psychiatry milestones represent a major paradigm shift in the overall approach that programs take to resident training and assessment because of their focus on outcomes and their specificity. Because of the process of development, they represent a true consensus of psychiatric educators regarding what residents need to accomplish and what programs need to teach. This shift in emphasis is not, however, without its critics. They have pointed out correctly that there is no evidence that utilization of the milestones will actually produce better psychiatrists. Detractors advocate resident assessment methods that are based on actual patient outcomes. The critics would prefer that there be no change in educational methods until prospective studies establish that there will be a positive outcome. Acceding to such objections would essentially guarantee that postgraduate education remains frozen in its current state. The ACGME has instead adopted a program based on modern quality improvement methods, essentially a PDSA cycle.



Version 2 Psychiatry Milestones, ACGME Report Worksheet

Patient Care 1: Psychiatric Evaluation
A: Gathers and organizes findings from the patient interview and mental status examination
B: Gathers and organizes data from collateral sources
C: Screens for risk and integrates risk assessment into the patient evaluation

Level 1	Level 2	Level 3	Level 4	Level 5
Collects general medical and psychiatric history and completes a mental status examination	Efficiently acquires an accurate and relevant history and performs a targeted examination customized to the patient's presentation	Uses hypothesis-driven information gathering to obtain complete, accurate, and relevant history	Elicits and observes subtle and unusual findings	Serves as a role model for gathering subtle and accurate findings from the patient and collateral sources
Collects relevant information from collateral sources	Selects appropriate laboratory and diagnostic tests	Interprets collateral information and test results to determine necessary additional steps	Interprets collateral information and test results to determine necessary additional steps in the evaluation of complex conditions	
Screens for risk of harm to self, to others, or by others	Engages in a basic risk assessment and basic safety planning	Incorporates risk and protective factors into the assessment of imminent, short, and long-term patient safety and the safety of others	Incorporates risk and protective factors into the assessment of complex patient presentations, including eliciting information not readily offered by the patient	Serves as a role model for risk assessment

Assessment of Residency Training Programs

The milestones were not only conceptualized as a method for evaluation of resident progress but are also intended to be used eventually as a method of programs evaluation, and there have been many other changes to the accreditation process.

Incorporation of Osteopathic Training Programs. The ACGME is now responsible for the accreditation of all residency training programs in the United States. In 2014, the American Osteopathic Association (AOA) entered into an agreement with the ACGME to consolidate the accreditation of osteopathic residency training programs under the ACGME. AOA accredited programs could elect to apply for ACGME accreditation until 2020. AOA specialty board certification for faculty in these programs was acceptable to the ACGME during the transition period. The programs transitioned to the ACGME may have a co-director certified by AOA specialty boards as long as the other co-director is ABMS-certified. The AOA and AACOM were integrated into the governance structure of the ACGME and are a nominating organization for candidates for membership on the RRCs. All of the RRCs that review AOA programs for accreditation have osteopathic members. By all accounts, this transition has been very successful. AOA programs that applied for ACGME accreditation achieved that status in 98.6% of cases. Graduating DOs success in the NRMP match has increased dramatically, with 99.29% placed either in the Match or through the NRMP's Supplemental Offer and Acceptance Program (SOAP). DOs now serve on the ACGME Board and on 20 of its RRCs (Table 57.1–16).

The Next Accreditation System (NAS). Previously, the ACGME fulfilled its accreditation responsibilities through a system of regular review of programs by the RRC. Data were collected every 5 years for programs in good standing. The PD wrote a Program Information File (PIF), which covered every aspect of program operation in relation to the ACGME PRs. A site visitor would travel to the program and confirm the PIF with interviews with the PD, residents, and faculty. The RRC would then review the data at its meetings, issue an accreditation decision, and issue citations for areas judged out of compliance with the PRs.

The accreditation process has been drastically altered under the NAS. Implemented for seven pilot specialties (emergency medicine, internal medicine, neurologic surgery, pediatrics, diagnostic radiology, and urology) in July of 2013, this system is now being used for all 26 ACGME core specialties. The NAS changes what has been described as a "biopsy" model into a program of annual data collection and review for every training program in the United States. The data sources for this review include an annual resident survey, faculty survey, and data entered by the program into the Accreditation Data Systems (ADS). For many specialties, case logs and board certification pass rates are reviewed annually. It is anticipated that aggregate data from the milestones will be incorporated into the accreditation system after enough experience has been gained.

Table 57.1–14. Psychiatry Milestones

Milestone Subcompetencies	**Threads**
Patient Care 1: Psychiatric Evaluation	A: Gathers and organizes findings from the patient interview and mental status examination B: Gathers and organizes data from collateral sources C: Screens for risk and integrates risk assessment into the patient evaluation
Patient Care 2: Psychiatric Formulation and Differential Diagnosis	A: Organizes and summarizes findings and generates differential diagnosis B: Identifies contributing factors and contextual features and creates a formulation C: Uses the emotional responses of clinician and patient as diagnostic information
Patient Care 3: Treatment Planning and Management	A: Creates treatment plan B: Monitors and revises treatment when indicated C: Incorporates the use of community resources
Patient Care 4: Psychotherapy	A: Establishes therapeutic alliance and manages boundaries B: Selects, sets goals, and provides psychotherapies including supportive, psychodynamic, and cognitive-behavioral C: Manages therapeutic process
Patient Care 5: Somatic Therapies (including Psychopharmacology and Neurostimulation Therapies)	A: Understands the mechanisms of action, indications, and evidence base for somatic therapies and appropriately applies them to patient care

	B: Educates patients about somatic therapies including access to accurate psychoeducational resources C: Appropriately monitors patient’s response to treatment
Patient Care 6: Clinical Consultation	
Medical Knowledge 1: Development through the Life Cycle (including the Impact of Psychopathology on the Trajectory of Development and Development on the Expression of Psychopathology)	A: Knowledge of human development B: Knowledge of pathologic and environmental influences on development
Medical Knowledge 2: Psychopathology (includes Knowledge of Diagnostic Criteria, Epidemiology, Pathophysiology, Course of Illness, Comorbidities, and Differential Diagnosis of Psychiatric Disorders, including Substance Use Disorders and Presentation of Psychiatric Disorders across the Life Cycle and in Diverse Patient Populations)	A: Knowledge to identify and treat psychiatric conditions B: Knowledge at the interface of psychiatry and the rest of medicine
Medical Knowledge 3: Clinical Neuroscience (includes Knowledge of Neurology, Neuropsychiatry, Neurodiagnostic Testing, and Relevant Neuroscience and their Application in Clinical Settings)	A: Neurodiagnostic and neuropsychological testing B: Neuropsychiatric comorbidity C: Application of neuroscientific findings in psychiatry
Medical Knowledge 4: Psychotherapy	A: Fundamentals B: Practice and indications C: Evidence base
Systems-Based Practice 1: Patient	A: Analyzes patient safety events

Safety and Quality Improvement	B: Appropriately discloses patient safety events C: Participates in quality improvement
Systems-Based Practice 2: System Navigation for Patient-Centered Care	A: Coordinates patient care B: Safely transitions care C: Population and community health needs
Systems-Based Practice 3: Physician Role in Health Care Systems	A: Understanding and working within the health care system B: Health care financing and advocacy C: Transition to practice
Practice-Based Learning and Improvement 1: Evidence-Based and Informed Practice	
Practice-Based Learning and Improvement 2: Reflective Practice and Commitment to Personal Growth	
Professionalism 1: Professional Behavior and Ethical Principles	
Professionalism 2: Accountability/Conscientiousness	
Professionalism 3: Well-Being	
Interpersonal and Communication Skills 1: Patient- and Family-Centered Communication	
Interpersonal and Communication Skills 2: Interprofessional and Team Communication	
Interpersonal and Communication Skills 3: Communication within Health Care Systems

Subspecialty Advisory Group (George Keepers, Chair)	Larry Faulkner, Frances Levin, Christopher Varley

Data from Accreditation Council for Graduate Medical Education. The Psychiatry Milestones.

The data from these sources are statistically analyzed by the ACGME, and outliers are identified for review on the basis of decision rules which are formulated by the RRCs. The data, program history, and previous ACGME actions are then reviewed by ACGME staff for presentation to the RRC. An RRC member conducts a review of the program and presents recommendations at the RRC meeting. The RRC may elect to continue the program's accreditation, continue accreditation with a warning, or ask for a site visit. Programs may be placed on probation following a site visit if problems with the program a very severe. The usual outcome of these reviews is to communicate to the program and its sponsoring institution that there are Areas for Improvement (AFIs) or to cite programs for noncompliance with the PPRs. AFIs are issues that may be dealt with by the program and its associated GMEC. Citations require, in addition, communication with the ACGME concerning the program's plan to remedy the problem. Programs with citations are automatically subject to annual review by the RRC.

Data from Accreditation Council for Graduate Medical Education. The Psychiatry Review Committee.

This system has the potential to identify and correct problems in training programs much earlier than the previous accreditation system. Additionally, its developers believe that it will encourage a more rapid pace of program improvement. Criticism of the new system has focused on the increased workload and expense required to comply with the new requirements and on the validity of the data, particularly the resident survey. PDs have expressed concern that residents are often confused by the questions on the resident survey and may answer the questions differently when properly oriented. Some studies do indicate that significant differences exist between the results from internal resident surveys and the ACGME resident survey. In 2019, the ACGME undertook the process of revising the resident and faculty surveys in response to these criticisms. A multidisciplinary task force and a commercial firm specializing in survey design completed this task. The revised surveys have been administered, and the results of the revision are being evaluated.

RELATION TO CHANGES IN MEDICAL EDUCATION

These changes in residency training are not occurring in isolation. The traditional system of medical education has been resistant to the incorporation of scientific developments in educational theory and performance improvement that have long been implemented in other educational and corporate settings. Future physicians can expect to be educated quite differently. Medical schools are incorporating the concepts of competency-based education and selecting students who will adapt better to the modern practices of team-based medicine. The requirement that students demonstrate competence at each stage of education is becoming universal. This will require a more flexible approach to the medical school curriculum than currently exists. For example, students matriculate to medical school at varying degrees of readiness. Flexible preparatory curricula are needed to meet varying student needs for additional education prior to their first day of medical school. Ideally, the goal is for every student and every resident to be uniformly excellent—to deserve an A grade. The purpose of competency-based undergraduate and graduate medical education is to raise the level of performance and reduce the variability in educational outcomes.

Following residency education and board certification, it is becoming mandatory that physicians maintain and improve their competence, incorporate new knowledge, and develop new skills throughout their careers. The ABMS and specialty board MOC programs are oriented to this goal. These developments in undergraduate, graduate, and postgraduate medical education are a veritable revolution in the way doctors will be educated. Medical education’s past has been one of discrete episodes of learning with little assurance that competence has been attained or will be maintained. Its future is as a lifelong learning process with feedback mechanisms ensuring that physicians practice at a uniformly excellent level.

57.2 Examining Professional Patients

M. SAGMAN KAYATEKIN, M.D., GEORGE BOMBEL, PH.D., AND KIM-LAN TRAN CZELUSTA, M.D.

In this chapter, we will talk about the development of a professional during his adulthood. More specifically, this is an attempt to think about human development, with a focus on professional development and how to think about the pauses and regressions in this ever-evolving process—if/when it may go off the tracks during later phases in life due to phase-specific challenges or personal problems like mental illness, substance abuse.

To illustrate the salient points in the professional maturation and growth chart, we will take a psychiatry resident during his residency training and then shift to a professional in their mature adult years, facing various roadblocks. The first section is specific to psychiatric residents. However, much of the discussion would generalize to other professions. Then, in the second section, we broaden our archetypical patient to include other professions.

Despite unique professional development trajectories, we believe that all professionals share expected psychological growth and cognitive development aspects. One crucial common denominator is that professional growth and development occurs in an interpersonal setting. This setting includes not only didactic learning but some form of apprenticeship. This approach is the solid foundation of any profession where there is a need for a supervised training period to develop competent professionals. This is more recognizable for those trained in psychiatry than in sister clinical fields such as medicine, psychology, social work, and nursing. However, it applies to many other fields of human education and professional skills; postgraduate studies in various areas, progression in military ranks or any organization, arts, becoming an artisan, craftsman, or a farmer.

In sum, humans learn and internalize their professional identities as they work, while being embedded in a matrix of a maturationally necessary asymmetric relation with others where information is transmitted through explicit (didactic education, bedside teaching) and implicit ways (identification with teachers as they are performing the tasks they are teaching the student).

PSYCHIATRIC RESIDENCY AS A MODEL OF PROFESSIONAL LEARNING, GROWTH, AND MATURATION

Starting Residency

Residency training is often the first employee situation for residents since many go directly from high school to college and medical school without a regular and sustained job. Unlike the occasional summer jobs, they may have held, working as a doctor, albeit in training, creates a highly complex nexus of relations, set of rules, regulations, and expectations that the young resident must learn, adapt to, and internalize. Thus, from the end of social role expectancies, these dynamics will reveal many capabilities and fragilities that were relatively dormant due to the person's straightforward, significantly simple interpersonal, and educational life during the "student" years.

It is an interesting dilemma that residents are professionally hybrid persons; although they are employees, they are also learners, which creates a complex web of supervision, milestones, and didactic education. Ultimately, the residency director is responsible for ensuring each resident will competently practice independently and with professionalism. Management of resident difficulties is one of the most time-consuming yet essential responsibilities for a residency director. In addition, the residency director balances complex and often conflicting issues related to fairness to the resident, the program, and the public. As the administrative requirements for residency training continue to increase, having a transparent process in place is essential to support both the residency director and the resident and promote the best outcome possible for all involved.

It is not uncommon for many trainees to have difficulty during these formative years of their professional development during residency. Some difficulties are straightforward and quickly addressed, while others can be extremely challenging, time-consuming, and stressful to all involved. The resident's status as both an employee and a trainee simultaneously guides and complicates addressing problems.

The residency program is poised to make training accommodations to support struggling trainees toward completing residency training. Common modifications include changing rotations or call schedules, increasing supervision, decreasing workload, or repeating a clinical experience. In addition, when approaching a resident's difficulty, the residency director is continually balancing three essential tenets: (1) fairness to the resident, (2) safety to the public, and (3) adherence to program policies to help each resident complete residency training.

Early Detection of Resident Difficulties

Data sources about resident performance include attending supervisors and chief residents, site-based directors, chiefs of service, on-call faculty, resident peers, administrative staff, patients, nurses, and other hospital staff. Documentation of the concern and subsequent intervention is essential as the concern may be the beginning of a series of later difficulties. In some cases, presenting concerns to the resident and supporting their efforts to reflect on their role in a conflict is a sufficient intervention. This will depend on the residents' openness and responsiveness to feedback.

A resident concern can have multiple contributing factors, and the residency director may not be able to address all etiologies at play. For instance, if the resident concern is a result of family or personal stressors (divorce, sick family member, family conflict), the residency director can offer emotional support in addition to referring to the institution's Psychiatric Counseling Service or Employee Assistance Program. The residency director could also consider temporarily reducing workload or work hours to allow the resident more time to address their situation. However, determining how long such a modified, reduced schedule is reasonable while ensuring the resident meets standard residency training and graduation expectations is not always easy to decipher.

If the resident's difficulty results from problems within the clinical unit or team members, the residency director can help elucidate and address the external factors resulting in residency difficulty. For instance, if the problem stems from a specific staff member of the clinical team with known concerns, then the residency director can provide feedback to the staff member's supervisor, who can then help intervene with the problematic staff member. Interpersonal difficulties with team members sometimes result from the confluence of different interpersonal styles that collide. In such cases, enlisting the help of the responsible attending or chief of the service may be warranted.

Most residents have a predictable developmental course during residency training, but some struggle more than others during the transition from medical student to intern. The increased patient care responsibilities combined with administrative tasks, new electronic medical records systems, teaching expectations, and more advanced specialty-specific clinical skills can be overwhelming and result in difficulties, including time management issues. Moving between large urban environments and small towns during medical school to residency training can also be jarring for some trainees. Lastly, leaving a familiar environment with established sources of support to move to a new surrounding with limited early social supports can be isolating.

Fit with the specific residency program may be a factor contributing to a difficult adjustment for residents. Fit encompasses many components and can include geographic location and program size, number of clinical sites and faculty, program culture, patient volume, typical work hours, and call type and frequency. Fit with specialty may be another factor contributing to resident difficulties as it is not uncommon for residents to change specialties in the middle of or after completing training in another specialty.

Finally, a resident’s psychopathology or medical illness can play a significant role in resident difficulties. Referral to the institution’s Psychiatric Counseling Service, Employee Assistance Program, or community provider offers treatment for the resident and provides information to assist the residency director in determining how to best support the resident. A medical leave of absence may be necessary to allow residents time to address their own health needs. The resident may not successfully meet the demands of residency training and successfully meet graduation requirements depending on the severity of the resident’s condition. Residents who have limited insight into their condition or are noncompliant with treatment recommendations can be especially vulnerable to difficulties.

When problems were noted, Dr. A was a PGY2 psychiatry resident who had excelled academically in her premed studies. She graduated Phi Beta Kappa from college, attended a competitive medical school where she was elected to the Alpha Omega Alpha Honor Medical Society, and then in the first few months, continued to perform at a clinical level that was higher than expected for residents at her level of training. However, her feedback became somewhat uneven in the Clinical Competency Committee meetings over the first 2 years of her residency training. The feedback ranged from "quick thinker, organized, focused, responsible, extreme fund of knowledge" to "challenging, immature, abrasive, poisonous attitude, disrespectful to team. doesn't see how her actions/words affect others."

This inconsistent feedback was difficult to convey, and much of it was informal, being relayed verbally to the program director. However, the resident's written evaluations were average or above average. When her residency director finally provided this feedback, Dr. An attributed the negative comments to mostly jealous and competitive peers and pointed out supervisors' above-average evaluations. During outpatient rotations of PGY3, Dr. A's work performance deteriorated further; she was frequently late to clinics and routinely late to close out electronic medical records. Since Dr. A worked at various outpatient clinic settings, the pattern of tardiness was not captured until the end of the PGY3 year.

Despite these various obstacles, the PGY4 year, which mainly was research electives, went relatively smoothly. Dr. A managed to graduate. She was not the stellar student her residency had hoped for but a young clinician with strengths and yet a fragility to develop split relationships. These relationships ranged from positive to negative, depending on the interpersonal context and task; she fared better in environments with a clear frame and comparatively limited close patient or staff contact. Patients' capacity to activate regressive individual tendencies and evoke split group dynamics with teams was overwhelming for Dr. A. After a process of beneficial psychotherapy and numerous consultations with her director and peers, following graduation, she chose to work in pharmacology research in a major corporation. It was a much less complicated interpersonal context where she could adapt with her introverted sides, and she fared well in this subbranch of her field.

PROFESSIONAL CRISES IN LATER YEARS

Clinical Phenomenology of the Loss of Sense of Self

We will not talk about specific pathologies and their treatment in this chapter—these are described in other chapters. Instead, we will focus on aspects of the clinical presentation and the treatment of "Professionals" that differentiate them from other social groups.

A standard, almost universal theme in the patients we see is the "loss of a sense of self." A lack of sense of self commonly accompanies a major depression or other major Axis I pathology. Nevertheless, some of our professional patients come without any severe pathology but just with a deep, painful sense of loss of self-definition, mainly in the context of a developmental-stage–related challenge.

Almost all of these patients we see have identified very deeply with their professional roles; their professional identity is "the" defining, core aspect of their self-images. Furthermore, this psychically vital element collapses due to exhaustion, common developmental challenges such as promotion or retirement, or major psychopathology.

The roots of this central and psychologically vital professional identification are somewhat complicated. Nevertheless, we describe some of the most common ones in the associated case descriptions.

Identification With Predecessors

A patient was in his mid-50s and was the heir apparent to a very successful business developed by her father and uncle. She was groomed very early on for this prestigious role, and the patient prepared herself well by attending Ivy League schools, doing a graduate degree in the field, and spending considerable time working on different parts of the organization during any off times from school. However, once she was actually in the leadership role, she had difficulties filling her predecessors' shoes and was constantly being critical of herself and being criticized by the family, hoping she would continue the family heritage. This ongoing discrepancy between the expectation and inability to fulfill it was one central root of her deterioration and hospitalization.

Disidentification

A 40s entrepreneur was from a humble background. His family had lower-class origins where the parents were rather lackadaisical about work, were into using substances, and did not care too much about raising family standards. The patient strongly disidentified with these aspects of his parents and developed a multimillion-dollar company over the years with hard work and luck. However, his only brother had identified with the parents, dropped out of college, and lived a marginal, parasitic life, lost in the world of drugs and multiple unsuccessful short-lived marriages. He committed suicide in his early 40s and following this unexpected horrific loss, around mid-career, the patient crumbled and became a person with no motivation for work, very similar to his brother, before he came to treatment.

Traumatic Abandonment

A successful doctor in his mid-40 s was hospitalized because of increasing exhaustion over excessive work. He described a sudden paternal loss at the age of early teens/puberty, following which his mother developed severe depression and the patient had to “grow” on his own and very fast; he worked two jobs to make ends meet, took care of his mother and continued his education. It was of note that he could remember little of his relationship with his father, and there was a strong undercurrent of chronic depression/grief that was helped enormously by repressing the painful grief defensively/adaptively in a hypomanic/obsessive way at work. He had accumulated enough wealth to retire by his mid-40s but then crumbled into a depression with a deep sense of “who am I.” He had lost a central, defining element of self that led to a 6-month hospitalization and then ongoing psychoanalytic treatment posthospitalization.

Central Defensive/Adaptive Styles of the Archetypal Professional Patient: the Hypomanic-Obsessive Style

A patient had a background of personal and transgenerational trauma due to immigration from a war zone, parental suicide, and neglect. He described an important adaptive aspect of excessive work quite poignantly; “I wake up with a deep sense of sadness and grief. Then in a matter of an hour, after taking a shower and having my breakfast, I immerse myself in my work, and all these painful feelings disappear. I work excessively and methodically till I exhaust myself and usually others around me. I can maintain my pace on 4 to 5 hours of sleep every day. This cycle repeats itself every morning, and when I can’t work, it becomes intolerably painful.”

Besides the centrality of defining oneself as a professional, we believe in a universal characterologic defensive/adaptive aspect of successful professional patients seen in specialty mental health programs geared toward professionals. This pattern includes the following typical constellation: prominent premorbid hypomanic character traits usually accompanied by obsessive-compulsive personality organizational aspects and a pattern of counter-dependence. For the sake of clinical shorthand, we name it as hypomanic-obsessive character organization. The collapse of this structure with defensive and adaptive elements leads to regression and the need for treatment.

The abundance of hypomanic-obsessive presentations in the patient population of our particular Professionals Program provides insights into this relatively neglected style of personality organization. It is as if these hypomanic traits, which allow a broad range of affect to be displayed in a diffusive way, are contained/constrained by obsessive substructures that are the other prominent aspect of personality organization. These patients can work endless days and hours—it is not unusual that a patient takes off only a few days over many years. As one of our patients suggested, "There is something very attractive about working and being successful at it. It is as if work has a way of expanding by itself, intruding into the person's life once the fulfillments are there". Moreover, these two elements of their personality structure fit well with their extreme independent/counter-dependent style of relating to others and problem-solving. One patient described this independent cognitive style as having "an internal debate" in decision-making instead of consulting with others.

The literature is abundant for mood disorders, yet hypomanic/hyperthymic presentations are somewhat in the margins of this literature. In addition, there is a debate on whether it is a bipolar spectrum disorder or a temperament. There is evidence that it has genetic connections to creativity. We do know that any illness can be used for defensive and adaptive purposes. Beyond its impact on the human body or psyche, in a person struggling with a chronic or repetitive illness, the person in consideration's body and mind adapt to this infringement and uses it in an adaptive/defensive manner. Here though, we see some temperamental/learned traits used for defense and adaptation and becoming the central defining element of the patient's personality.

In common parlance, this is what is coined rather loosely as the concept of "workaholism." What the typical jargon, of course, misses is the fact that this is not an aspect of the character structure that can be extirpated for treatment, but it is an essential capability of the human mind that can be used more adaptively if it can be brought under the proverbial "domain of the ego." In an interpersonal level, when operating properly, hypomanic/obsessive style provides the person with extremes of independence, a capacity to make significant decisions on their own without the need for group-think that is more common in successful professionals that lead teams of various sizes—from a clinical team to a large organization.

In their detailed life histories, we notice that there are some standard developmental patterns in these patients. Bypassing multiple adolescent developmental tasks is a common element. There is a distorted, stunted, bypassed adolescent growth; a typical pattern is a very early love relationship; they become devoted lovers/friends and join their lives with the person they met in high school or early college years. Thus, they lack a core group of friends; their spouse usually is their “best friend.”

Family relationships, time with friends, and other “fun” activities are sorely missing for these patients. Everything they do is tied to an ultimate aim of developing a perfect result—as a professional or parent. They are pervasively result-focused, and, in their worldview, “fun” activities with no purpose are an enigma for them. Paradoxically, they display social anxieties and almost a tendency to schizoid isolation when there is no central work-related task. These core mild schizoid-social phobic aspects are somewhat dormant side by side with impressive capacities to work and be very social within workgroups and lead them to success.

They usually treat their nonwork-related aspects of life with the same principles they successfully utilize in work. Thus, having a final product of a perfect marriage and shining kids becomes a powerful motive. These interpersonal patterns are “counter dependent” in that the patient relates to persons as if they were objects. This approach is very similar to their successful cognitive work modus operandi—they treat job-related issues in meticulous detail with an impressive capacity to make decisions almost singlehandedly—in a fiercely independent intellectual functioning. Similarly, they treat relationships in a nonpersonal distant way and try to fix, find algorithmic solutions, and may even be extremely helpful with their close relationships’ decision-making.

Finally, in the background developmental history, quite regularly, there is a history of attachment trauma, parental loss, the transmission of trauma across generations, and unresolved grief, which usually begins around the preadolescent teens.

Clinical Phenomenology of the Decompensation of the Hypomanic-Obsessive Defensive Style

Once regression sets in, three aspects of the presentation stand out: The mood becomes somber, depressed with an agonizing absence of “who they are." The obsessive sides shift to a deep incapacitating ambivalence, ambitendence, and ruminations, losing all its impressive analyzing/problem-solving qualities. Finally, the patient develops the presentation of deep sadness, apathy, preoccupation with guilt-ridden ruminations, and extremes of dependence which is the polar opposite of their usual functioning self.

The hypomanic/obsessive style deteriorates to an obsessive/ruminative style and may even lead to precatatonic, and in rare instances, catatonic states.

One of our patients, a 40-year-old businessman, described the progression into catatonia wonderfully. The first sign was a sense of increased anxiety—contextual, concerning conflict within a love relationship, or work-related conflict. Then he recognized a slowing and perseveration of his thought processes and speed. This slowing led to difficulty in building sentences and a general, painful slowing of his psychomotor functioning. Moreover, the crux of the crisis was when he became entirely immobile with thoughts, themes circling in his mind, unable to decide to move around or stay still. He could stay like that for a day. He would be exhausted from keeping a rigid posture and not eating or drinking. As a result, he was hospitalized a few times. Occasionally he would be able to break this agonizing immobile state and pull himself out of the freezing. This syndrome was clearly articulated by earlier clinicians like Kahlbaum and resembled an advanced form of obsessive indecisiveness, ambivalence, and ambitendence.

An example of a milder case is a 70-year-old patient who had fully retired after a successful career. He was observed "stuck" in the doorway to his room on our professional treatment unit. He attempted to go in, took a few steps toward the bedroom, and then walked out of the bedroom a few steps toward the hallway. When we inquired about this, he said he was torn between wanting to go toward and away from his room. He thus repeatedly walked in and out endlessly.

On a more profound level, the following case exemplifies the tormenting state of ambivalence. The patient, a gentleman in his 60s with a very typical hypomanic/obsessive personality style, was tremendously successful in his line of work. Following retirement, he became depressed. This depression was characterized by the loss of self-definition around his identity as a professional. He decided to come to the hospital after some years of toying with the idea, and it took him about another year-plus to make up his mind after making a final decision to come to the campus. However, it was almost impossible for him to initiate the admissions process once in the building. He could not get in through the doorway of the admissions building. He was stuck. He was begging to be admitted, and a second later, he was telling us that he could not be admitted because he was too sick and needed to be admitted to a locked facility. He then begged that we send him to such a unit as he began lying down and writhing, rolling around on the floor in agonizing anxiety. Finally, after the patient spent a few days in involuntary treatment (that we had initiated), he returned and managed to bring himself to the unit despite a paralyzing sense of indecisiveness and ambivalence.

Once in the unit, he displayed similar symptoms on more subdued and subtler intrapsychic and interpersonal levels. He managed to keep himself in the program but wore down the staff’s patience by constantly asking whether he would be transferred again to a locked unit. His indecisiveness was at a level where he would seek guidance on ordinary daily chores, such as on which medications to choose or which foods to eat. Once he got the recommendation on the medication or the food, he would immediately start thinking about the ill effects of the pill or the food he had chosen, become regretful, and try to change his mind again. No ordinary logic counterargument was of any help, and he was aware of this, and this self-awareness made him more ashamed of his behavior. With intense treatment, he slowly cleared from this depressive/obsessive/indecisive pit and maintained a much higher level of functioning in the unit.

For many patients, the painful ruminations flooding their minds when regressing were rooted in beneficial aspects of their cognitive organization when focused and controlled. Premorbid, these patients usually do not have an obsessive-compulsive disorder but rather an obsessive-compulsive personality structure. Their meticulousness with details and ability to weigh options were such that they were admired for their analytical skills and their precise decision-making capabilities. However, this solution-oriented cognitive functioning began displaying a “broken record” quality when decompensated, and there was no processing but futile repetition of similar themes. So, the crumbling of the hypomanic-obsessive defensive/adaptive structure and the accompanying loss of sense of a central definition of self would add to the patient’s problems and worsen the patient’s depression.

TREATMENT: UNFOLDING INTO THE SYSTEM, REPEATING THE STORIES OF THEIR LIVES

This chapter will focus on some unique aspects of the treatment specific to this clinical population. However, standard treatments, such as psychopharmacologic agents, should be used when appropriate. Also, sleep problems are pervasive and can be treated with cognitive-behavioral therapy for insomnia (CBTi) or appropriate medications. For older professionals, cognitive evaluations are essential. In our experience, it is rare not to treat patients with some standard psychiatric treatment.

Our repeated experience is that psychotherapeutic approaches and biologic treatments work on similar neural substrates and, if appropriately combined, tend to potentiate one another. In the last few decades, the worldwide increase in moving away from monolithic and exclusionary/antagonistic “biologic” versus “psychological” theories toward more integrative theories of mind and mental illness is a witness to this fundamental, paradigmatic shift.

Some Central Therapeutic Elements of This Unique Setting

Repetition is one primary key—one way to evaluate these patients’ intrapsychic/interpersonal scripts is how they unfold into professionals’ programs and repeat their central issues: conflicts, deficits, interpersonal modii of operandi. A central dynamic is the externalization of internal representational scripts in the form of; seeing the self in staff and peers, seeing the object in staff and peers, group dynamics that unfold with peers, and transferences to hospital. Enactments and clearing from enactments are central to treatment.

Due to the therapeutically regressive elements (limited time, relative confinement to a physical space with other peers, intense group dynamics, regressive pulls of therapies), there is rapid individual/group regression, and the patient presents intrapsychic and interpersonal functioning with relative transparency in the milieu.

The psychotherapeutic hospital is an environment where the patient constantly tests functional beliefs, distortions, and expectations. As a result, various transference, countertransference, and enactment scenarios develop and are lived through and interpreted.

Patients report that it is much easier to open up and talk about their experiences honestly in the hospital setting because they feel a sense of belonging when they hear the stories of fellow patients—the pathologically grandiose fantasy that they are alone, the only one with this kind of embarrassing mental health problem dissipates very rapidly. It becomes a more ordinary and shared experience.

As well-established research demonstrates, psychotherapeutic hospitals, which offer more extended immersion into various psychotherapy and biologic therapies, are conduits of impressive and promising change. However, in essence, we probably still do not have a refined, satisfactory theory of how these unique human ecologies work.

As a demonstration of an approach to treat professional patients, the remainder of this chapter will describe a representative case in detail.

Treatment Example: Marvin

Marvin was a divorced, 60-year-old and CFO of a technology company with a vague history of anxiety, dysphoria, perfectionism, and aloofness. From his perspective, he was primarily content and healthy aside from intermittent “blue spells” over the years. These spells were quickly ameliorated with medication changes; however, 6 months before the current series of inpatient psychiatric treatments, he decided to “preretire” to escape a painful work situation and spend more time with his wife, two adult children, and several grandchildren. This retirement involved stepping down from CFO to a part-time consultant to the company’s board, a move that immediately left him feeling empty, directionless, worthless, and psychologically collapsed. In turn, he became overwhelmed with regret and severe rumination about the decision to preretire. Dread, anxiety, and dysphoria overtook him, and he became suicidal—eventually culminating in suicide attempts. After the most recent (benzodiazepine overdose), he was admitted to a crisis-stabilization unit in his city, then transferred to a partial hospital program.

PSYCHOLOGICAL ASSESSMENT. As a part of a thorough evaluation, Marvin’s treatment team requested a psychological assessment to clarify stressors, defenses, interpersonal relations, thought processes, coping capacities, and diagnosis, and to receive treatment recommendations. Marvin participated in a clinical interview, then completed the Millon Clinical Multiaxial Inventory—4th Edition (MCMI-IV), the Thematic Apperception Test (TAT), and the Rorschach Inkblot Test, using the Rorschach Performance Assessment System (R-PAS) administration and scoring guidelines. During the assessment sessions, Marvin presented with a fragile but determined grin that was insufficient to mask his underlying dysphoria. His thought process was ruminative, focusing on the loss of his CFO role, and recent marital conflicts. Nevertheless, he remained tense, polite, cooperative, and engaged throughout the process, though mildly condescending at times and doubtful that the assessment would provide any new insights about how his mind works.

The assessment data suggested that, behind his defensive functioning, Marvin felt fundamentally inadequate, broadly ineffective, emotionally weak, and flawed in significant ways. For example, despite his successes, he described feeling socially inept and awkward in most life spheres (with friends, family, colleagues). Concomitantly, he tended to suspect that others are ever-poised to hurt, criticize, reject, shame, humiliate, or deceive him—so he was pretty suspicious, though he did not appear to reach the threshold for clinical paranoia. These perceptions of self and others left him shy, apprehensive, and racked with self-doubt. Marvin's primary strategy for managing this pain, uncertainty, and fear was an avoidance pervasive and robust enough to resemble schizoid withdrawal. Thus, on the surface, he appeared distant, aloof, emotionally detached, or even indifferent to others—and although willing to engage in some obligatory family and business engagements, he appeared to prefer solitary activities. However, this presentation was more reflective of assiduous efforts to deny longings for closeness and approval to neutralize the internal conflict, for example, if he had no desire, he did not need attachments and therefore could not truly be hurt. Broadly, in concert with natural human longings for social contact and acceptance, Marvin's insecurities oriented him toward others (e.g., for soothing, comforting, approval, mirroring), while the suspiciousness motivated him to avoid or withdraw, behaviorally and emotionally. Therefore, he was highly conflicted about closeness, or even about establishing superficial relationships, unless approval and deep appreciation (and safety) could somehow be guaranteed.

Upon this defensive stratum rested another that addressed Marvin's painful self-concept directly, fueled in part by internalized family (of origin) expectations that he succeeds tremendously, attends the best schools and receive academic honors, become a CEO, and be the family's source of pride and healing; that is, he felt compelled to succeed to save the family from its shame or humiliation based on their immigration status (originally from Eastern Europe)—or else he risked drowning in his shame and humiliation (and theirs), as a disappointment and a failure. This painful internal terrain prompted him to adopt an idealized self-image as an elite super-achiever: An enterprising, enlightened, and inspired businessman who worked tirelessly, motivated colleagues and mentees, and accomplished what others could not. Other facets of this self-image were more compulsive; for instance, he worked to see himself—and be seen by others—as a serious-minded, disciplined, efficient, and industrious individual who was reliable and committed to work, productivity, and the bottom line. Accordingly, he was loath to appear frivolous or rash, terrified of making mistakes, or perceived as exercising poor judgment. Self-control was paramount; he presented as “buttoned up,” self-sufficient, and entirely in control of his needs, impulses, emotions, and behavior. Any acknowledgment or display of emotional pain or vulnerability would be too exposing, dangerous, shameful, and unbearable since, for him, it would be tantamount to broadcasting the inadequacy, weakness, and defectiveness he secretly felt but worked so intensely to escape or deny.

Given the stakes—instability of self-esteem/worth and the potential for excruciating exposure and shame—Marvin was compelled to extend his domain of control to include others. As suggested, this included managing his public and even private personas so that others only perceived what he wanted them to perceive (a superior, industrious, controlled super-achiever). In this way, he could have his greatness reflected, an unconscious psychological maneuver that effectively dispatched his most profound painful self-concept. Ideally, essential others (e.g., family members, mentees) would shine as well, as good reflections of him, but they were devalued or pushed away if they disappointed him or began to approach or eclipse his status. Marvin generally managed others by setting high expectations and being pushy and demanding. However, when his status or authority was challenged, control over others was somehow lost, or he felt disrespected, he was capable of direct or indirect retaliatory verbal aggression. These outbursts served to discharge his rage but also to push others back into line.

However, these measures intermittently failed during the “blue spells” or when stressors severely taxed Marvin’s limited coping resources. For example, when he had few mentees at work and felt less idealized. Alternatively, when a new junior manager publicly questioned his decisions, which challenged his sense of superiority and made him feel criticized, humiliated, and quietly furious. Similarly, when his adult children complained that he showed little interest in spending time with his grandchildren, he was left feeling criticized, ashamed, and resentful. These factors combined to motivate the “preretirement” to escape the painful work environment and have more opportunities to demonstrate that he was the “super grandpa” associated with his persona of exceptionality. However, he was unable to predict how the part-time consultant position would ultimately fail to “fill [his] sails,” provide worth and direction, neutralize his emptiness, and buttress his fragile sense of self (as inadequate, weak, defective, socially inept). He subsequently collapsed and was overrun by waves of regret and uncontrollable rumination about having made “the worst decision of my life!” Unfortunately, his defense of aloofness, superiority, self-sufficiency, and invulnerability made him a closed system, that is, he desperately longed for soothing, comfort, and relief from his pain within loving relationships wherein he is known but was unable to drop his armor. Ultimately, this has left him feeling dreadfully alone, misunderstood, resentful, and disillusioned with life, leading to his suicidal ideation and attempts.

Marvin’s assessment data and presenting symptomatology suggested the following diagnoses for consideration (from Diagnostic and Statistical Manual of Mental Disorders—5th Edition [DSM-5]): Major depressive disorder, recurrent; and other specified personality disorder with narcissistic and obsessive-compulsive personality traits.

Based on the assessment data, Marvin received treatment recommendations for short and long-term psychotherapy work. The team suggested that Marvin would benefit from time-limited cognitive-behavioral approaches (CBT) in the short term. These approaches could focus on modifying his painful intermediate and core beliefs (e.g., I am inadequate, weak, and defective; letting others see my vulnerabilities would be disastrous; anything less than being a super-achiever is an utter failure; I know best, so people should do things my way). These approaches could also help him retrain his attentional processes to register more accurate data that would allow him to develop reality-based, realistic, compassionate concepts of self and others.

In the longer-term psychotherapy work to initiate structural change (2 to 3× week psychodynamic psychotherapy), it was suggested that Marvin address his relationship templates and attachment style more immediately within the psychotherapy relationship itself—since they would inevitably surface there. After a basic alliance was established, the therapy focus could become more expressive, during which the therapist could explore Marvin’s feelings and relationship patterns more deeply. Given the nature of Marvin’s developmental arrest, it would be necessary for the therapist to communicate empathy about Marvin’s need for mirroring and to help him understand the links between (a) early deprivations, (b) his current hunger and emotional pain, and (c) the efforts to elicit signals from others that he is great, superior, admirable—including how he utilizes control to achieve this objective. It would also be imperative for the therapist to register and acknowledge their intermittent failures at providing this empathy. This cyclical therapy process—empathizing/mirroring, then recognizing and processing Marvin's painful feelings (e.g., grief, shame, humiliation, hopelessness, rage) when mirroring failures occur—would allow, over time, his current insecure sense of self to gain traction and resume its developmental trajectory.

PSYCHOTHERAPY. Marvin's individual psychotherapy consisted of a series of 15 sessions with a psychodynamic therapist, occurring three times per week throughout treatment. His original goals were to learn techniques to "manage the anxiety and depression and get back to have a contented life with my family"—a typical set of goals for the large subset of professional patients who present with a blend of compulsivity or perfectionism and narcissism. These individuals tend to fantasize that their struggles are mechanical problems that can be easily loaded into an algorithm that provides a quick solution. Not surprisingly, therefore, Marvin grumbled during the developmental history because he could not understand how his childhood experiences—including early, crucial attachment relationships—had any bearing on the current struggles. Similarly, he minimized the importance of addressing his recent suicidal ideation and suicide attempts because he no longer felt suicidal and was confident he would control any ideation and impulses that might occur again in the future. Consequently, he declined offers for a Collaborative Assessment and Management of Suicidality (CAMS) session.

He begrudgingly tolerated these deeper inquiries by the therapist but occasionally protested the lack of focus on immediate symptoms. A few times, he went so far as to suggest that the therapist was either incompetent or withholding effective (quick) treatments that were otherwise available. Here, Marvin responded moderately well to efforts by the therapist to highlight and challenge (a) his underlying fantasy that his mind is merely a contraption to be hacked and solved, and (b) his distorted perception that the therapist would be interested or motivated to withhold better treatments than were being provided. Marvin preferred to repeatedly describe his immediate psychiatric symptoms, such as anergia, anhedonia, low motivation, intermittent insomnia due to rumination, hopelessness, self-criticism, guilt, and regret, difficulty concentrating, and anxiety and tension secondary to catastrophic thinking. However, the most painful symptoms were the most difficult for him to describe and label. This process became a focus during the initial phase of psychotherapy. For example, he started making conceptual and emotional links between (a) the subjective emptiness, purposelessness, and worthlessness he felt overwhelmed by (and could now label) and (b) the decision to give up the CFO position that provided such buttressing and direction, but also opportunities to receive precious admiration and mirroring.

These insights paved the way for Marvin to begin noticing how robust was his use of control—to restrict his emotions, to ensure that others only ever perceived him as an astute leader, responsive mentor, and as an individual who was admirable, impressive, serious, disciplined, industrious, and entirely in control of himself. Marvin and the therapist explored how this defensive strategy manifested itself with family members, coworkers, in the milieu with fellow patients, and in the therapy relationship itself. For example, the therapist repeatedly pointed out when Marvin tried to impress her with tales about business adventures that indicated how accomplished, productive, and efficient he was; or when he tried to present himself as unusually informed about the epidemiology of specific mental disorders. Here, she made sure to interpret Marvin’s tendency to present his super-persona as a desperate effort to flee direct contact with his deeper self-image as inadequate, weak, defective, and shameful. Around this time in the individual work, he received push-back from fellow patients about his aloofness, invulnerability, and efforts to impress. In concert, these external relational forces moved Marvin to begin softening his compulsive-narcissistic armor, which then paved the way for him to become a little more vulnerable, and therefore more willing to authentically express despair, regret, and sadness about having decided to preretire. Notably, only then did he become capable of making emotional links between the painful self-concept (defective, weak), his subjective experience of emptiness, and the pressure he felt to save the family (of origin) from their shame and humiliation about their immigration status by becoming a super-achiever.

These insights altered the trajectory of Marvin’s healing journey. He eventually replaced his original psychotherapy goals (“manage anxiety and depression”) with a set of more nuanced and sophisticated goals for the psychotherapy work while still on the professionals unit and going forward. These new goals focused on addressing his underlying sense of inadequacy, correcting his distorted perceptions of others, and reducing his reliance on compulsive-narcissistic armor. He also started to come to terms with the fact that he lived most of his life feeling utterly responsible for saving the family system from shame and humiliation—and in the process, disowned or discarded parts of himself.

PSYCHOTHERAPY PROCESS GROUP. Throughout his treatment, Marvin attended a twice-weekly psychotherapy process group (80 minutes each session) based on a group-as-a-while interpretation model based broadly on the work of Wilfred Bion. In this adapted model, the group explores interpersonal communication, group dynamics, and group-as-a-whole processes, with particular attention to how the group manages anxiety about connecting in the here-and-now. Reliably, when group members feel safest, the group is most cohesive, so unconscious worries about the group's disintegration are in their lowest ebb—a condition that inclines group members to explore how they are relating to each other during the session. This level of connection requires the most significant vulnerability and is relatively rare because it involves exploring perceptions of each other and associated emotions in real time. This can include acknowledging and expressing caring and warmth, regret, sadness, hurt and anger, or envy. In this "safe" mode, group members are more inclined to share a great deal of detail about their internal struggles and the suffering that brought them to residential treatment.

In contrast, when group members feel less safe, the group is less cohesive, and unconscious worries about the disintegration of the group are ascendant—a mode that leaves members feeling insecure, too vulnerable to share details about their suffering, and more inclined to discuss superficial topics (e.g., the weather). Alternatively, they might unconsciously decide to complete the task of connecting in the here-and-now by forcing themselves into faux cohesion by finding a common enemy to rail against, for example, a political figure, a scapegoated staff member, the mental health system. Invariably, individual group members end up occupying roles (such as peacemaker, leader, outsider, helpless one) they adopted in their families of origin to reduce anxiety by nudging the process group toward cohesion or faux cohesion. In this model, the group "therapist" is not a facilitator, per se, but a consultant to working on the task. Consultations or interpretations are primarily directed toward the group-as-a-whole, for example, pointing out how the members have silently colluded to enlist one particular member to take up all the space with a monologue about his business history so that the group can avoid exploring and processing sadness they feel about the impending discharge of another beloved member. The ultimate goal of this approach is to help group members create the conditions for authentic connection and healing through emotional closeness and vulnerability. This goal is more likely to occur as group members learn more about how groups, in general, manage anxieties about working on a task and as each group member learns more about how they participate in these group-as-a-whole processes.

Given Marvin's defenses of aloofness, superiority, self-sufficiency, and invulnerability, he was slow to warm up to the psychotherapy process group experience. He declined initial offers by group members to share his reasons for coming to treatment. As they shared, he mainly remained quiet and disengaged, frequently looking out the large windows, lost in thought. After a few sessions, he began joining the group in some lighter conversations about experiences at work before treatment, though he limited his participation to noting some of his business accomplishments and describing how he has needed to "put some of my disrespectful underlings in their place." Members did not respond with open admiration, which frustrated him. Perhaps in response to this deprivation, he appeared to try moving into the role of wise elder by offering platitudes and problem-solving when members discussed their struggles. Some members were receptive and appreciative, while others saw through his defensive maneuvering and resented his superior stance, especially given that he had thus far avoided sharing anything deeply personal or painful. However, this resentment remained underground despite a few consultations about how the group seemed terrified of conflict and determined to ignore or deny palpable emotions in the room. Eventually, the dynamic shifted when the group added a new member (Libby) who was not particularly conflict-avoidant and was willing to articulate her frustration with Marvin about his persona of wisdom and invulnerability. In one group, she exclaimed: "You're like Gandalf or something, above it all…but I don't buy it. I think you're actually lonely. You'd have to be!" Her tone was both critical and caring. Marvin responded by referring to some of her recent dramatic behavior on the unit as "earth-mother histrionics." Other group members, emboldened by Libby's bravery, stepped into voice some of their pent-up frustrations about Marvin's superiority and inaccessibility, but also their desire to know him better, which he seemed to register. Notably, the discussion continued after the group ended and the consultant left the room. Three days later, much of the group tension was gone in the following group session, and Marvin began talking for the first time about the waves of regret and loss following his decision to preretire. His rumination and reassurance-seeking began to emerge, and members provided understanding and verbal support, which enabled him to become tearful during a later group session. In response to interventions in the group and milieu, he was becoming less of a closed system, for example, less aloof, more vulnerable, more able to allow himself to receive from others.

TERMINATION. After an 8-week stay, Marvin was asymptomatic. He left the hospital with an alternative plan of developing a part-time individual consulting practice and a self-help group therapy for higher managers going through burnout—it was an interesting outcome, a way of sharing his experience in the hospital with the less informed and perhaps less fortunate. On a personal level, Marvin continued his treatment with intensive psychodynamic work, group therapy, and medication management. Two years later, we had a call from him and learned that he was doing quite well.

Ethics and Forensic Psychiatry

58.1 Clinical-Legal Issues in Psychiatry

CLARENCE WATSON, J.D., M.D., SPENCER ETH, M.D., AND GREGORY B. LEONG, M.D.

Among the medical specialties, psychiatry plays a particularly distinct role within the province of the law, given its potential application across a wide range of legal issues. Contained at the core of most legal principles is the general presumption that adults of sound mind possess the capacity to understand, appreciate, reason, and choose throughout a boundless range of life activities. When those mental capacities are called into question at the behest of a legal quandary, psychiatry may be summoned to assist with reaching an equitable resolution. The presence or absence of a mental health or cognitive disorder may significantly impact the manner that a legal issue, whether civil or criminal, is perceived and ultimately managed. For instance, the presence of major mood or psychotic symptoms may impact an individual's legal right to refuse a recommended surgical procedure. Similarly, the presence of significant psychiatric symptoms at the time of a criminal act may negate an individual's culpability for that offense. The enduring relationship between the law and psychiatry has evolved over the centuries as a necessary element of humankind's aspiration toward a just resolution of legal disputes. In no other place is this more evident than with the historical development of the legal concept of insanity in criminal law. Once reserved only for those individuals whose minds were equated with that of a wild beast, the legal concept of insanity has progressed to varied jurisdictional approaches in determining the degree of mental impairment necessary to absolve an individual of criminal responsibility. Equally as significant is the historical development of the doctor–patient relationship. Once considered a lopsided paternalistic arrangement, in which patients were expected to passively accept the medical care directed by their physicians, the doctor–patient relationship has matured into a dynamic interaction that centers on patients' autonomy, including a patient's right to refuse treatment.

From an eagle's eye view, the interplay between psychiatry and the law can be broadly divided into situations involving clinical treatment interactions and situations involving specific legal matters that require the input of psychiatrists to settle a contested legal issue. The complexities within this broad division cannot be overstated, and accordingly, the subspecialty of forensic psychiatry was, in essence, produced from necessity and the ever-developing legal landscape. Clinical-legal issues such as patient confidentiality, informed consent, the right to refuse treatment, and medical standards of care are ubiquitous in the psychiatrist–patient therapeutic relationship. Potential involvement by psychiatrists as experts in contested legal matters, such as criminal cases, personal injury lawsuits, employment-related claims, testamentary disputes, or child custody cases, requires familiarity with legal principles and jurisdictional laws and the ability to apply psychiatric knowledge to the relevant legal inquiry at hand.

Over the course of centuries, the unique pirouette shared between psychiatry and the law has at times lacked grace, but nonetheless, has steadily moved toward a more elegant cooperative existence. Often marked by tensions inherent in speaking different native tongues of the respective realms of medicine and law, the cooperative existence has benefited from both medical and legal literature aimed at bridging the gap. This chapter is meant to contribute to those literary efforts and offers common ground for the understanding of clinical-legal issues involving psychiatry.

THE DOCTOR–PATIENT RELATIONSHIP

The concept of the doctor–patient relationship is naturally bound to the ancient roots of medicine itself. Evolving from a period when physicians were not distinguished from priests, magicians, or other ancient healers, the doctor–patient relationship initially resembled an archaic priest–supplicant relationship that hinged on a parental figure's power to manipulate nature on behalf of his ward. During the 4th century BC, the Hippocratic Oath set forth a code of ethics outlining principles that remain essential features of modern-day medical ethics, including patient confidentiality, abstaining from sexual contact with patients, and preventing harm to patients. The familiar dictum, *Primum non nocere* or first, do no harm, further distilled the fundamental ethical principle at the core of the doctor–patient relationship.

Clearly, at the heart of these traditional ethical doctrines, physicians are charged with acting only in the service of patients' medical benefit. The ethical principle of beneficence, where the ultimate medical benefit is paramount, was traditionally used to justify a paternalistic approach to medical care that was primarily physician-driven. However, during the late 19th and early 20th centuries, there was a growing sentiment that patients had the right to actively influence the course of their medical care. The concept of patient autonomy gradually gained ground and ultimately displaced the long-accepted institution of medical paternalism.

Patient autonomy was clearly endorsed in the 1914 case, Schloendorff v. Society of New York Hospital, which served as the figurative "canary in the coalmine" for medical paternalism in the dawn of an evolving informed consent doctrine. In that case, Justice Benjamin Cardozo ruled, "Every human being of adult years and sound mind has a right to determine what shall be done with his own body . . ." While not formally established in Schloendorff, the informed consent doctrine would become a more clearly defined legal requirement four decades later in the 1957 Salgo v. Leland Stanford Jr. University Board of Trustees case.

Certainly, at the inception of any doctor–patient relationship, there attaches a body of legal and ethical obligations owed by the physician to his patient. The shift away from medical paternalism toward the incorporation of patient autonomy permitted a more appropriate balance within the therapeutic relationship. Such a balance between a physician and his patient naturally facilitates a treatment partnership; however, there are clinical situations that call for prioritizing medical benefit over patient autonomy. Justice Cardozo's words in Schloendorff indicated his awareness of two important caveats regarding the “right to determine what shall be done” with one’s own body: adulthood and soundness of mind. It follows, of course, that the impact of existing psychiatric symptoms must be considered in the full clinical context when issues related to patient autonomy arise. Medical decision-making capacity, involuntary psychiatric treatment considerations, and patient confidentiality matters may all be influenced by the presence of significant psychiatric symptoms that temporarily deemphasize autonomy concerns.

MEDICAL DECISION-MAKING AND COMPETENCE

As initially framed in Salgo v. Leland Stanford Jr. University Board of Trustees, the law requires that physicians provide facts to their patients regarding treatment options that are “. . . necessary to form the basis of an intelligent consent.” Through this case law, the informed consent doctrine was established and formed a basis for physician liability when patient harm occurs in the setting of inadequate communication of the risks associated with treatment. In order to sufficiently obtain a patient’s informed consent, three elements must be present: the physician’s disclosure, the patient’s voluntariness, and the patient’s mental competence. Exceptions to the informed consent requirement include medical emergency, patient’s waiver of the physician’s disclosure requirement, and invocation of therapeutic privilege in situations where the disclosed information would be detrimental to the patient.

Generally, the informed consent disclosure requirement dictates that patients receive information regarding their diagnosis, the proposed treatment with the associated risks and benefits, treatment alternatives, and likely consequences of declining treatment. The 1972 case, Canterbury v. Spence, established that physician liability may be found if there is a causal connection between a physician’s failure to disclose and a patient’s injury, where the disclosure of the significant risks of treatment would have resulted in the patient’s refusal of that treatment. According to the court in Canterbury, that causal connection is based on “…what a prudent person in the patient’s position would have decided if suitably informed of all perils bearing significance.”

Depending on the state jurisdiction, the legal standard for an adequate disclosure may vary between a physician-based standard and a patient-based standard. In states that utilize a physician-based approach, doctors are required to provide information to patients that a reasonable physician in his specialty would disclose. States that utilize a patient-based approach may require an objective standard that considers the information that a reasonable patient similarly situated would want to know to reach a decision. Some states may require a subjective analysis of the patient-based standard that considers the information that the specific patient would want to know given their circumstances.

The voluntariness requirement directs that a patient be permitted to weigh the disclosed information and reach a decision unencumbered by coercion. Accordingly, threats, manipulation, or intentionally misleading information during a patient's decision-making efforts would nullify informed consent. A patient must be given the opportunity to freely consider the physician's disclosure and freely reach a medical decision.

The competency element requires that a patient possesses the mental capacity to understand, appreciate, and utilize disclosed information to reach a rational decision. Legally, all adults enjoy a presumption of competence in medical decision-making and other routine life activities until adjudicated otherwise. Traditionally, the term "competence" is a judicial determination regarding decision-making capability. Conversely, the term "capacity" refers to a clinical determination regarding a patient's decision-making abilities. Accordingly, the psychiatrist's role in competency evaluations is to determine an individual's mental capacity, which may later be formally adjudicated in a legal competency proceeding. In contested matters, courts have upheld the rights of a competent adult to refuse treatment. Courts may, however, adjudicate a person as incompetent if psychiatric symptoms or cognitive deficits impair an individual's mental capacity to communicate a choice, to demonstrate factual understanding and appreciation of his situation, or to rationally manipulate factual information related to his situation. In cases of adjudicated incompetence, treatment decisions generally shift from the patient into the hands of a substitute decision-maker or designated guardian.

Significant symptoms of mental illness or cognitive disorders are the typical culprits that undermine competence. However, the presence of those symptoms alone is not sufficient to establish a lack of mental capacity or to prove incompetence. In the 1973 case, In re Maida Yetter, a patient who was committed to a state psychiatric hospital refused treatment for possible breast cancer. Although delusional, the patient offered a rationale that justified her treatment refusal and allowed the court to determine that she was competent to make that decision independently and did not require a substitute decision-maker.

A controversial area related to medical decision-making capacity involves questions surrounding a terminally ill patient's right to die and physician-assisted death. Currently, ten states (Oregon, Washington, Vermont, California, Colorado, Hawaii, New Jersey, Maine, Montana, and New Mexico) and the District of Columbia legally permit physician-assisted death. In jurisdictions allowing terminally ill patients to choose physician-assisted life-ending measures, psychiatrists may be called upon to perform mental capacity assessments relating to those decisions.

INVOLUNTARY HOSPITALIZATION AND TREATMENT

Two traditional legal justifications, *parens patriae* and police power, provide state jurisdictions with the authority to involuntarily hospitalize or civilly commit mentally ill people for the purpose of treatment. *Parens patriae* refers to governmental power to care for individuals who are unable to care for themselves. The initial application of the parens patriae principle for the care of the mentally ill in the United States is found in the 1845 case, In re Oakes, which established the basis for courts to involuntarily hospitalize mentally ill persons for treatment and to prevent harm. The police power principle refers to the societal interest of permitting governmental authority to protect the general public from potential harm.

Jurisdictional statutes regarding involuntary psychiatric hospitalization vary from state to state but generally require the presence of a mental illness and a degree of risk of harm to the patient or to others due to the patient's symptoms of mental illness. Typically, the clinical determination for the necessity of civil commitment weighs a patient's current symptoms, relevant historical information, and collateral information sources (e.g., family members, friends, etc.) in the setting of a patient's inability or unwillingness to cooperate with the examination. During these assessments, the critical issue that must be addressed is whether patients' current psychiatric symptoms place them at risk of harming themselves or others. Additionally, some jurisdictions specifically require that involuntary treatment be implemented via the least restrictive alternatives available. Accordingly, clinical consideration must be given to alternatives to involuntary inpatient hospitalization, such as day treatment programs, group home placement, or other outpatient settings, depending on the circumstances.

Usually, these civil commitment assessments involve emergency situations in which family members, ambulance personnel, or police bring the patient to the emergency department because of concerns that the patient will imminently engage in suicidal, self-injurious, or violent behaviors. In addition, a voluntary patient might demand an immediate hospital discharge against medical advice and compel the psychiatrist to consider whether a civil commitment is necessary in lieu of discharge. Due to the urgency of these clinical situations, civil commitment laws permit clinicians to initiate involuntary emergency hospitalization without an initial court determination. This allows for immediate and necessary treatment interventions without the delay that awaiting a court hearing would cause. Following a statutorily determined period, a judicial review hearing is typically required to weigh the patient's need for continued involuntary hospitalization versus a patient's right to be discharged from inpatient treatment.

The legal standard of proof in civil commitment proceedings is "clear and convincing," which is less than the "beyond a reasonable doubt" standard in criminal trials. It is important to note that involuntary hospitalization does not per se permit medical treatment over patients' objections. Some jurisdictions require additional legal proceedings to permit the involuntary administration of medication over patients' objections. Following adequate treatment targeting the symptoms that necessitated the civil commitment, the patient may be discharged to the community to continue outpatient treatment. In some states, patients with extensive histories of treatment nonadherence and frequent hospitalizations may be evaluated prior to discharge for the appropriateness of outpatient civil commitment in order to improve community functioning.

In addition to standard civil commitment laws for psychiatric treatment, some states have enacted specialized civil commitment laws for the involuntary treatment of violent sex offenders who continue to pose a risk of danger following incarceration. In 1997, the U.S. Supreme Court upheld the constitutionality of sex offender civil commitment laws. Under these specialized provisions, these convicted and incarcerated sex offenders are evaluated prior to their prison release to determine if commitment criteria are present, including the existence of a congenital or acquired mental abnormality, the number and severity of previous sexual offenses, and dangerousness.

Psychiatrists cannot lose sight of the inherently intrusive nature of involuntary treatment. Accordingly, clinicians are ethically obligated to exercise due diligence in obtaining all relevant clinical data prior to determining the need for civil commitment. The psychiatrist continues to bear the ethical obligation of avoiding unnecessary breaches of patient confidentiality. However, testimony and communications to mental health courts required by law for the purpose of civil commitment are permitted without patient consent. Nonetheless, clinical efforts to preserve patient dignity and foster a therapeutic alliance with the patient remain paramount.

CONFIDENTIALITY AND PRIVILEGE

Confidentiality and privilege are related concepts that center on privacy rights belonging to patients regarding information shared with their physicians during the course of therapeutic relationships. Confidentiality represents physicians' obligation to their patients to not disclose information to third parties without a patient's consent. Privilege also deals with the protection of patient information; however, it refers to the more specific protection against physicians being compelled to provide protected patient information during court proceedings. Privilege is a right that specifically belongs to the patient, in that a physician cannot claim the privilege and refuse to disclose patient information once a patient has waived the privilege.

The doctrine of patient confidentiality is an ethical and legal duty that has been long recognized throughout the tradition of medicine, as evidenced by the Hippocratic Oath's charge to preserve patient privacy. Certainly, it is not difficult to understand the basis for this duty. The very nature of the doctor–patient relationship prompts patients to trust physicians with intimate details of their lives, relationships, and bodies for the purpose of medical treatment. Patients' candid communication of these details facilitates effective medical treatment and would likely be discouraged if physicians were free to reveal those details publicly.

Physicians may be held liable for breaches of patient confidentiality through legal theories of medical malpractice, invasion of privacy, and breach of contract for implied warranty of confidentiality. State legislatures have also enacted statutes that prohibit the unauthorized release of patient information. Accordingly, physicians may also be held liable for the breach of statutory duty of confidentiality. In addition, the U.S. Congress enacted the Health Insurance Portability and Accountability Act of 1996 (HIPAA), which provides a set of privacy regulations that govern the electronic transmission of health information for insurance eligibility and billing purposes. Psychiatrists should note that the practice of telepsychiatry also falls under HIPAA regulations. Accordingly, psychiatrists must ensure that their videoconferencing systems are compliant with HIPAA and state privacy requirements. Violations of HIPAA privacy regulations call for the imposition of fines. However, these regulations do not provide compensation to patients impacted by confidentiality breaches.

There are several exceptions to the confidentiality duty owed to patients by their psychiatrists. First, disclosures by psychiatrists without patient consent may be permitted in emergency situations in order to prevent imminent harm. Second, psychiatrists may breach confidentiality when acting to protect third parties from a potentially dangerous patient. In 1976, the California Supreme Court decided Tarasoff v. Regents of the University of California, which set into motion a nationwide trend establishing the duty of mental health professionals to protect or warn their patients' potential victims or to notify police of a risk of danger posed by a patient. Laws regarding the duty to warn or protect third parties vary by state jurisdiction and are defined by state statutory and case law. These laws provide an avenue for clinician liability if harm befalls a third party as a result of a mental health professional's failure to disclose the danger posed by their patient. Generally, disclosures made in good faith for the purpose of protecting the third party will not result in liability for breach of confidentiality. Third, psychiatrists may disclose patient information when adhering to state reporting requirements involving concerns such as child or elder abuse, unsafe drivers, or impaired health care professionals.

The physician–patient and psychotherapist–patient privilege doctrines evolved from the historical legal prohibition of compelled testimony from attorneys against their clients. The basis of that legal tradition was to protect the sanctity of the attorney–client relationship, which would be effectively eviscerated if lawyers could be forced to testify against the very clients that they represented. Much like the justification for requiring patient confidentiality, the physician–patient, and psychotherapist–patient privilege facilitate a more open and effective therapeutic alliance. In all state jurisdictions, patients possess the legal privilege to prevent their psychiatrists and psychotherapists from testifying about them. Federal courts also recognized patients' privilege following the U.S. Supreme Court's 1996 ruling in Jaffee v. Redmond. As the privilege belongs solely to the patient, psychiatrists have no basis for refusing to testify if their patients choose to waive that privilege.

However, the privilege is not absolute and may be pierced under a number of circumstances, thereby paving the road to compelled testimony by treating psychiatrists. Patients may lose the privilege in cases where they raise their mental status as an issue in a civil or criminal matter. Medical malpractice claims initiated by patients against their psychiatrists or therapists would also remove the privilege. The privilege does not apply in civil commitment proceedings. In child custody cases, the privilege may be set aside if the best interests of the child outweigh the negative impact of the psychiatrist's testimony. Finally, the privilege could be potentially nullified if the patient shared the information in question with their physician in the presence of a third party who is not involved in the patient's care.

PSYCHIATRIC MALPRACTICE

Psychiatrists tend to dread malpractice lawsuits in excess of the statistical likelihood of being sued and having a judgment entered against them. Across all medical specialties, there has been a major reduction in the rate of paid malpractice liability claims during the last decade, which, unfortunately, has not been accompanied by commensurate decreases in the cost of malpractice insurance policies. There are approximately ten paid claims for every 1,000 American allopathic physicians each year. By contrast, however, the Institute of Medicine estimates that more than 100,000 Americans die annually from medical mistakes, and about 6% of patients are injured by medical mismanagement. Recent data reveal that among an extremely large sample of physicians, malpractice actions cluster in a relatively small percentage: 89% of physicians had no malpractice claims, about 9% had only one claim, while the remaining 2% or so had two or more claims that amounted to nearly 40% of the total claims. Psychiatrists experienced about 4% of all claims, commensurate with their representation of 3.6% of the total sample of physicians.

About half of malpractice claims filed are litigated. Of these claims, courts dismiss more than half, and another 40% are resolved before a trial verdict. The remaining small minority of cases become jury trials, of which 80% result in a defense verdict favoring the physician. Nationally, the mean time for resolution of a litigated malpractice claim is 2 years, which has grown considerably because of the backlog of cases associated with COVID restrictions affecting many aspects of the legal process, particularly jury trials. In one large state, about 2% of all malpractice settlement reports were for psychiatrists, compared with 9% for internists and 10% for general surgeons. The majority of malpractice actions filed against psychiatrists derive from accusations of negligent treatment, adverse effects of prescribed medications, and suicidal and assaultive behavior of patients. The remainder mostly concerns alleged mistakes in diagnosis, breaches of confidentiality, and boundary violations. A psychiatrist’s participation in a malpractice settlement exceeding a threshold amount will result in a mandatory report to the federal National Practitioner Data Bank (NPDB), an entity that was first authorized in 1986 as a repository for information such as adverse licensure and hospital actions, and health care providers’ malpractice payments. NPDB entries are routinely accessed by hospitals and licensing boards and may trigger inquiries that cause discomfort for physicians who may have felt unfairly coerced to agree to a settlement.

The theory of medical malpractice refers to professional negligence that falls within the civil law domain, as defined by state statutes and case law. For example, in Florida, patients or their representatives may file lawsuits for personal injury or wrongful death against health care providers. In those malpractice actions, plaintiffs must prove by a preponderance of the evidence that the actions of the provider represented a breach of the prevailing professional standard of care. The standard of care in this context is a legal term that refers to skillful treatment, which in light of all relevant circumstances, is recognized as acceptable and appropriate by reasonably prudent providers in the same specialty, such as practicing psychiatrists.

The law recognizes that the mere existence of an injury does not automatically imply that provider negligence occurred without proof that the provider did, in fact, breach the standard of care. A bad outcome does not per se equate to bad care. An exception to this rule is the legal concept, *res ipso locquitor* or the thing speaks for itself, where the commission of an egregious error, such as failing to remove an abdominal clamp during surgery, shifts the burden of proof from the plaintiff to the defendant physician to show that negligence did not occur. For psychiatrists, such an egregious error would certainly include sexual misconduct during a therapy session under the guise of treatment.

The necessary elements for patients to successfully establish malpractice claims have been neatly summarized as encompassing four D’s: duty, dereliction, direct causation, and damages. The duty element requires that a doctor–patient relationship had been established, thereby creating a duty of care. Although seemingly straightforward for most treatment situations, there are some instances in which the nature of the professional relationship can be vague. Does a duty begin with the first contact between a potential patient and psychiatrist setting an appointment over the phone or only after the initial in-person or telehealth virtual platform meeting? When does the duty terminate? Does a covering physician assume responsibility for a patient if the patient calls for a medication refill or is seen briefly on rounds over the weekend?

The element of dereliction refers to a breach of the duty to provide reasonable and appropriate care. Psychiatrists are not legally expected to offer perfect, state of the art, or even excellent diagnostic and treatment services. All that is required is for the psychiatrist to perform as would other psychiatrists facing the same patient. Being board certified in psychiatry is neither necessary nor sufficient to establish that no deviation from the standard of care has occurred. It may be useful to demonstrate compliance with authoritative treatises, such as the Comprehensive Textbook of Psychiatry, recent peer-reviewed publications, or professional association treatment guidelines. However, it is an accepted principle that every person is unique and, consequently, patient-centered care may call for modifications in the usual therapeutic approach. Prescription medications are dispensed with package inserts containing information drug companies have submitted to the Food and Drug Administration (FDA). However, physicians are under no legal requirement to adhere to what is in the package insert and have substantial deference in prescribing “off label” as called in their clinical practices. Indeed, perhaps half of patients prescribed the common psychotropic medications are receiving them for off-label indications. Accordingly, a clinical judgment that adequately accounts for a patient's full clinical context, despite an eventual bad outcome, would likely assist in buffering against a claim of dereliction. When proposing an unusual treatment plan that may be later questioned, the psychiatrist would ordinarily be expected to obtain informed consent from the patient. The details of the consent discussion should be carefully inscribed in the medical record, and it may be helpful for patients to sign a note documenting their understanding and agreement.

The direct causation element requires a direct causal connection between a breach of the standard of care and a subsequent patient injury. The term "causation" is one that may have conceptually different meanings in medicine and law. For scientific-minded physicians, a cause–effect relationship identifies that a particular prior event is the physical cause if it results in the later effect. The law takes a very different approach. The salient issue is the proximate cause, by which the focus of the legal inquiry is whether the act in question was necessary to produce the injury. A common test for direct causation is whether the harm would not have occurred "but for" the prior action.

Legal commentators have argued that direct causation is that necessary element of a set of conditions that are jointly sufficient for the result. For example, a psychiatrist's older adult patient endorsed symptoms of depression, weakness, postural instability, and osteoporosis. The patient fell to the floor while rising from the office couch at the end of a session and immediately complained of severe pain. The patient was taken to a local hospital emergency room and diagnosed with a hip fracture. Surgery was performed, but the patient developed a postoperative infection that ultimately proved fatal. This tragic chain of events undoubtedly had multiple underlying medical causes. However, from a legal perspective, the psychiatrist could be found to be negligent and the proximate cause for all of the patient's subsequent injuries and death. Depending on the facts, the crux of the matter may be that, but for the mishap while rising from the psychiatrist's couch, the patient would not have had a broken hip, surgery, an infection, and death. In this regard, the patient was surely an "eggshell" whose fall was the "straw that broke the camel's back." As lawyers are fond of saying, one takes plaintiffs just as you find them.

The damages element refers to the plaintiff's alleged injuries that resulted from the physician's dereliction of duty. Civil law recognizes several categories of damages that may accrue to victims of malpractice, all of which are exclusively financial. Monetary awards to successful plaintiffs are intended to compensate the plaintiff for the harm suffered. Compensatory damages address what the patient has suffered as a direct consequence of the substandard care and include present and future medical costs, lost income, physical and mental impairment, pain and suffering, and decreased life expectancy. Punitive damages, also known as exemplary damages, may be awarded in addition to compensatory damages when a defendant's behavior was found to be particularly egregious or malicious. Punitive damages are not meant to compensate a plaintiff's loss; instead, they are meant to punish the defendant and to serve as a deterrent to the defendant and others regarding similarly wanton behavior. Punitive damages, which are not covered by insurance, rarely arise in malpractice actions against physicians.

The specter of serial medical malpractice claims, analogous to mass tort litigation, became a grim reality in the aftermath of the conviction of a Michigan State University (MSU) sports physician for sexually abusing multiple young women under the guise of treatment. MSU agreed to pay $500 million to 332 alleged victims, thereby settling their lawsuits without a trial. The University of Southern California (USC) was faced with at least 1,700 claims of sexual misconduct during gynecologic examinations by a physician practicing for many years in the campus student health clinic. The two negotiated and court-approved settlements for the USC student plaintiffs totaled $1.1 billion. These universities had employed the physicians and were thus ultimately responsible for the damages inflicted under the legal theory of *respondeat superior* that holds an employer liable for employees' wrongful or negligent acts. The "deep pocket" universities were the target of civil legal action, while the physicians were pursued separately and aggressively by the criminal justice system.

Certain aspects of psychiatric practice involve a greater risk of liability. Electroconvulsive therapy (ECT) is a procedure that usually calls for additional training and special precautions and may be associated with a greater likelihood of adverse events than conducting a psychotherapy session. Consequently, psychiatrists who wish to perform ECT may need to purchase insurance policies that specifically cover this procedure. Prescribing certain psychiatric medications also warrants a cautious approach. Conventional antipsychotic medications place patients at risk of developing tardive dyskinesia, which, when severe, can be disfiguring and disabling. Successful malpractice cases have been filed when psychiatrists failed to alert patients of this side effect risk and neglected to perform and document routine examinations for its detection. Similarly, the use of atypical antipsychotic medications may call for routine assessments for weight gain and abnormalities of blood lipid and glucose metabolism in addition to patient discussions regarding these associated treatment risks. Increasingly, psychiatrists use formal education materials to supplement informed consent discussions when prescribing common psychotropic medications, such as benzodiazepines, stimulants, and lithium.

The specter of patient suicide affects all practicing psychiatrists; indeed, it is a truism in the field that there are two kinds of psychiatrists—those who have already had a patient commit suicide and those who will. Rather than encouraging fatalism, the ever-present danger of suicide for certain groups of patients should motivate psychiatrists to remain cognizant of the basic suicide-reducing strategies. Knowledge of the evolving epidemiology of suicidal behavior is fundamental in assessing static and dynamic risk factors for each patient. There is no question that asking patients about the presence and severity of depressive symptoms and suicidal thoughts is essential for proper care. Such direct inquires do not suggest to or predispose a patient to become actively suicidal. The Joint Commission has suggested the implementation of standardized suicide risk assessment instruments, such as the Columbia-Suicide Severity Rating Scale (C-SSRS), that can be embedded as mandatory fields in electronic note templates so that clinicians must explicitly address the issue of suicidal ideation in settings such as the emergency room. Psychiatrists must respond to the escalating risk of suicidality with very careful monitoring and appropriate modifications in the treatment plan.

No discussion of psychiatric malpractice is complete without consideration of boundaries. Much has been written about the conscious and unconscious forces that are in play in both patient and psychiatrist during a session, especially in the context of psychotherapy. Maintaining the integrity of the therapeutic frame, however challenging, is the linchpin of treatment. Of particular concern are boundary violations that constitute frank lapses in care, such as psychiatrists becoming romantically involved with a current or former patient. This boundary violation is usually characterized by a progression from a seemingly innocent conversation, to more frequent social contacts, to physical affection, to sexual activity. In these cases, psychiatrists can exhibit remarkable denial regarding the serious consequences of their own behavior. Not infrequently, a transgressing psychiatrist, such as one who may be lonely, depressed, and substance-abusing, begins a destructive relationship with a vulnerable patient, whose judgment may be impaired by an idealizing transference and self-defeating tendencies. Such unethical behavior may result in malpractice and licensing board actions that jeopardize a professional career.

THE PSYCHIATRIST AS AN EXPERT

Expert Witness Testimony

Psychiatrists may be asked to participate in civil and criminal court matters by providing professional opinions based on their psychiatric knowledge and experience as applied to a particular legal question. Typically, the opinions are provided to a requesting party, generally the court or an attorney, either as a written or oral report. In some instances, the opining psychiatrist is required to testify in court, with a jury or judge considering such testimony along with other evidence in order to reach a verdict. Psychiatric expert testimony takes place in the public purview and is often viewed by the public as a “battle of the experts” or, more pejoratively, battle of “hired guns.”

In some cases, expert witness testimony is legally required, such as in cases involving allegations of medical malpractice. For example, in order to support a medical malpractice claim that a defendant psychiatrist’s treatment led to a patient’s suicide, the plaintiff must present expert testimony to show what a psychiatrist of ordinary skill, care, and diligence would have done differently under similar circumstances. Of course, should this malpractice case go to trial, there may also be psychiatric expert witnesses testifying on behalf of the defendant psychiatrist. Two court cases have governed the admissibility of scientific expert testimony in the United States, Frye v. United States and Daubert v. Merrell Dow Pharmaceuticals, Inc. As both cases indicate, it is ultimately the judge’s decision as to the admissibility of the expert witness testimony.

Role Conflict as a Psychiatric Expert Witness

The fundamental professional role of psychiatrists involves a clinical or therapeutic perspective. In the clinical or therapeutic setting, the treating psychiatrist deals with the patient's narrative truth and makes no further attempts at confirming a patient's statements. In contrast, when a psychiatrist works outside of the health care setting in the legal arena, the clinical or therapeutic perspective loses its primacy, and an individual's self-report should be viewed with objectivity and hence skepticism. Assuming both the therapeutic and expert witness roles for the same individual invite erosion of the psychiatrist–patient relationship, whether it involves completing a disability evaluation in which the treating psychiatrist does not find support for the requested disability, or especially in the case of testifying in court as a psychiatric expert witness.

Separating the therapeutic and forensic roles is the best solution, though, at times, the dual role cannot be avoided, as in the case of involuntary civil commitment or involuntary medication hearings in which the treating psychiatrist is usually the only professional to testify. There are times in which a treating psychiatrist could be called to testify as a fact witness regarding a patient, but this would entail testifying about symptoms, diagnosis, prognosis, and similar clinical matters versus providing the ultimate psychiatric-legal opinion such as those involving capacity or causation.

Testamentary Capacity

With the growth of the older adult population, psychiatrists are being confronted with an increasing incidence of its emblematic mental condition, dementia, and the related clinical-legal issues of capacity and competence. Although adults are assumed to have capacity for the various activities of daily living and life tasks, that presumption is rebuttable, especially in the presence of neurocognitive impairment. Each specific deliberative legal act, such as testifying in court as a witness, executing a financial transaction, and even getting married, has its own criteria for mental capacity that must be satisfied in order for that action to be valid. Among the older adults, the process of writing a last will and testament is a common and highly valued event that has important implications that will arise after the death of the testator.

Legislatures and courts recognize that making a will is frequently in the province of persons whose mental acuity is significantly less than young individuals engaged in other tasks. Consequently, the cognitive standard for testamentary capacity is generally set particularly low. In most jurisdictions, the necessary elements are that persons understand: (1) the fact that they are actually making a will, (2) the nature and extent of their property, (3) the disposition of that property, and (4) who are their natural heirs. From a mental status perspective, this domain of knowledge does not require that the person making the will is fully oriented and, indeed, having the diagnosis of Alzheimer disease per se would not disqualify a person from having sufficient cognitive ability to make or change a will if the criteria for testamentary capacity could be established.

Although simple to state, the prerequisite criteria for testamentary capacity may be, in practice, quite difficult to ascertain after a person's death when the will is finally read. For instance, a person could have been suffering from severe dementia at the time of death. However, the document was actually prepared years earlier, and it is the state of mind at the time when the will was written that is dispositive if the document is later contested. A retrospective assessment conducted after death is challenging when there is inadequate evidence of the individual's prior knowledge and abilities. Medical records, deposition testimony from relatives and acquaintances, and information about activities of daily living can contribute to a determination of capacity.

Since wills may be the product of debilitated older adult persons who depend on the physical and medical care of others, there is another requirement that must be satisfied before the terms of the will are honored. Testamentary capacity demands that the testator not be subject to the undue influence of another person. For example, the philanthropist Brooke Astor died at the age of 105 in 2007. Her older adult son was convicted in criminal court of preying upon his mother's diminished mental state by defrauding her in life and coercing her to change her will in his favor rather than directing her assets to her favorite art institutions. An adult child who spends considerable time with a vulnerable parent may be expressing love and devotion. Alternatively, that situation may be exploited to benefit the child at the parent's expense.

Psychiatrists may be asked to opine whether a litigant heir exerted control over the person making a will. Certainly, whether there existed a confidential relationship and whether the will was rewritten to inappropriately benefit that person are critical factors. In this setting, a "confidential relationship" between two individuals occurs when one of the parties has an obligation to act in good faith for the benefit of the other party. The psychiatrist's expertise will be most relevant to the question of the extent to which the testator was vulnerable to being influenced due to medical or psychiatric illness and the power of the asymmetric relationship.

Criminal Competencies

The presence of competent decision-making is necessary for a criminal defendant navigating the criminal justice process, starting from the initial arrest to the implementation of the death penalty. While competence is presumed for adults, the presence of a mental disorder may negate competence. The criminal competencies include: competency to waive Miranda rights, competency to confess, competency to stand trial, and competency to be executed.

The U.S. Constitution and its Amendments, along with subsequent federal and state case law and statutes, delineate the legal safeguards for individuals accused of committing crimes. At the entry point into the criminal justice system, law enforcement officials must inform a criminal suspect of their Miranda rights, such as the right to remain silent and the right to counsel. The presence of an active mental disorder or intellectual disability can negate an individual's capacity to voluntarily, knowingly, and intelligently waive their Miranda rights. Though very few adults lack the capacity to waive their Miranda rights, the majority of incompetence to waive Miranda rights involves juveniles where factors such as immaturity and emotional vulnerability are more likely to adversely impact voluntariness, knowledge, and/or intelligence. The competency to confess might be considered under the broader competence to waive Miranda rights. In 1986, the U.S. Supreme Court in Connelly v. Colorado ruled that absent physical coercion by police, an actively psychotic individual, who approached a police officer to confess about committing a homicide as a result of command auditory hallucinations to confess, had provided a valid confession.

The most common forensic psychiatric evaluation in the criminal justice system is that of competence to stand trial. The criteria for competence to stand trial is guided by several U.S. Supreme Court decisions, with two having the most significance, Dusky v. U.S. (1960) and Godinez v. Moran (1993). The Dusky case established that competency to stand trial is composed of two prongs: (1) understanding of the criminal proceedings; and (2) reasonable ability to consult with defense counsel. In the Godinez case, the court ruled that if criminal defendants are competent to stand trial, they are also competent for other activities in criminal proceedings, such as the competence to waive counsel, competence to enter a plea (waive trial), and competence to be sentenced.

For jurisdictions that permit capital punishment, the U.S. Supreme Court has mandated certain exclusions to the imposition of the death penalty, including mental retardation (now referred to as Intellectual Disability in the DSM-5-TR) in Atkins v. Virginia in 2002 and for those under age 18 at the time of committing the capital offense in Roper v. Simmons in 2005. The U.S. Supreme Court in Ford v. Wainwright in 1986 and Panetti v. Quarterman in 2007 prohibited the execution of condemned inmates who are incompetent to be executed. Incompetence to be executed involves a condemned inmates' inability due to a mental disorder to understand the death penalty and the reason it is being imposed on them. Although cases of competence to be executed are quite rare, it has raised several ethical issues for society and the medical profession.

Criminal Responsibility and Psychiatric Illness

The determination of culpability and subsequent societal sanctions for those committing a criminal act finds its origins at least as far back as the dawn of recorded human history, along with considerations given to those with abnormal mental conditions. The evolution of English law in the area of criminal responsibility of the mentally disordered over the past millennium has exerted great influence on how criminal responsibility has been determined in the United States. Although the number of psychiatric evaluations for defendants claiming that a mental condition negated their criminal responsibility for an offense accounts for a small proportion of evaluations performed for the criminal justice system, the issue of criminal responsibility of those with mental disorders is arguably the most visible to the general public due to extensive media coverage, both fictional and nonfictional.

To be proven guilty of committing a crime, the prosecution must prove beyond a reasonable doubt that the accused person not only committed a prohibited act (*actus reus*) but also had the requisite mental state or "guilty mind" (*mens rea*) for the forbidden act.

The insanity defense is used to prove that an individual did not possess the necessary mental state for criminal responsibility due to mental illness at the time of the act. From the preceding millennium, the concepts of the “wild beast test” and the ability to distinguish between good and evil (right and wrong) represented society’s efforts to legally define “insanity.” These efforts evolved and culminated in the formulation of the M’Naghten insanity standard in 1843 by the English House of Lords following an insanity acquittal in the English trial of Daniel M’Naghten. The M’Naghten insanity test required the defendant to prove that they were “laboring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or, if he did know it, that he did not know he was doing what was wrong.” The M’Naghten standard was quickly adopted for use by the U.S. judicial system. The federal government, the District of Columbia, and 46 states permit some form of the insanity defense. Among the 46 states that permit the insanity defense, approximately half use a M’Naghten type of insanity test. Four states (Montana, Idaho, Utah, and Kansas) disallow the insanity defense. In 2020, the U.S. Supreme Court affirmed that states are not required to provide an insanity defense (Kahler v. Kansas).

While the majority of state jurisdictions use the M’Naghten insanity standard, some states use other insanity tests. Currently, the most common other type of insanity test is that of the American Law Institute (ALI). To qualify for insanity under the ALI insanity test, a criminal defendant must demonstrate that as a result of a mental disorder, they lack “substantial capacity to either appreciate the criminality of his conduct or to conform his conduct to the requirements of the law” (Model Penal Code §4.01, 1962). When comparing the two current major insanity tests used in the United States, the M’Naghten test has two “cognitive” prongs (knowledge of the “nature and quality” and “wrongfulness”) versus ALI’s one “cognitive” prong (“appreciate the criminality”) and one “volitional” prong (“conform conduct”). Interestingly, some states that use an ALI-type of insanity test do not use the “volitional prong,” thereby functionally making the insanity standard more like the M’Naghten test. Wording differences between the M’Naghten and ALI insanity tests would suggest that an insanity defense would be more likely successful in jurisdictions using the ALI insanity test.

In actuality, the overall use of the insanity defense is infrequent. The defense is raised in approximately 1% of felony cases with an estimated 25% success rate. The vast majority of insanity acquittals involve prosecutorial concurrence prior to trial. It is estimated that juries reject the insanity defense in 93% of cases going to trial. It has been argued that the legal system's requirement to not inform juries of the potential legal consequence of an insanity acquittal, that is, that a defendant acquitted by insanity would not be automatically released into the community, but would be subject to commitment in a state mental health facility, adversely impacts jurors' willingness to accept insanity defenses.

CHILDREN AND THE LAW

Children and adolescents can become enmeshed in the U.S. legal system in a multitude of ways, some of which are comparable to adults, and some are fundamentally different. In fact, the number of youth involved in court actions has increased dramatically, driven by criminal activity in gangs and on their own, by the escalating rates of foster care, divorce, and custody disputes, and by the proliferation of child abuse neglect, and victimization. Further, there continues a veritable parade of personal injury lawsuits filed on behalf of child victims that alleged harm from sexual misconduct by generations of clergy, teachers, and others. Psychiatrists would benefit from a familiarity of the basic concepts of children and the law, if for no other reason than to better understand their adult patients whose early histories may be replete with such encounters and whose younger family members may become entangled in some aspect of the law.

Children, Juvenile Justice, and Violence

Juveniles can be both perpetrators and victims of crimes. The indisputable developmental differences between prepubertal children and adolescents, and especially adults, have legal implications insofar as cognitive phase-specific limitations of youth accused of criminal behavior would seem to necessitate special measures if not an entirely different method of adjudication. Indeed, states created parallel juvenile justice systems for youthful offenders that, in many ways, were responsive to the developmental immaturity that characterizes children and younger adolescents. In 1899, Illinois established the first juvenile court separating the adjudication and confinement of youth as delinquents from the conviction and imprisonment of adults as criminals. The scope of juvenile courts expanded to encompass both criminal acts and behaviors that would not be considered illegal for adults, such as curfew violations, drinking alcohol, and truancy, which have been called status (as a minor) offenses. The rationale for juvenile courts' broad jurisdiction is the promotion of social warfare by prioritizing education and rehabilitation rather than punishment.

Every state proceeded to adopt a system of juvenile courts, whose procedures were then significantly modified by the Supreme Court's landmark cases under Chief Justice Earl Warren. In 1967, the U.S. Supreme Court held that, although it was permissible to treat juveniles and adults differently in court, youthful offenders facing possible incarceration are entitled to the same constitutional rights of notice of charges, counsel, protection from self-incrimination, and the opportunity to confront and cross-examine witnesses, as afforded to adults. Three years later, the Supreme Court also ruled that the "beyond a reasonable doubt" standard of proof also applied in juvenile court. Extending constitutionally based procedural rights to juveniles did not imply that juveniles could escape conviction and punishment, especially if they committed serious crimes. Prosecutors have the discretion to file for a judicial waiver that moves the youth from juvenile court to adult court in order to deny the protections that juvenile jurisdictions provide, including the preclusion of long prison sentences.

Most states exclude first-degree murder charges from the juvenile system, which for many years effectively allowed a convicted juvenile murderer to be sentenced to execution. The eligibility of a person who committed their crime as an adolescent for capital punishment proved to be controversial even among death penalty advocates. The Supreme Court reviewed the question of juvenile capital punishment and decided in Roper v. Simmons (2005) that defendants were not eligible for execution if their crimes were committed under the age of 18 years. The court's opinion in this decision drew heavily on scientific data concerning neuropsychological development that contrasted adolescents with adults, which were presented in amicus briefs submitted by psychiatric and psychological professional organizations. Five years later, the Court, in Graham v. Florida (2010), held that the U.S. Constitution prohibits sentences of life without parole for juvenile offenders who did not commit homicide. In those cases, a juvenile offender is not guaranteed eventual release, but if a life sentence is imposed, the juvenile must be afforded a realistic opportunity to obtain release before the end of that sentence. In Miller v. Alabama (2012), the U.S. Supreme Court extended its reasoning to preclude as unconstitutional a mandatory sentence of life without the possibility of parole for juveniles convicted of homicide offenses.

The Columbine High School tragedy in 1999 engendered an awareness of a looming threat of mass killings occurring in a school, possibly perpetrated by an adolescent or young adult. Despite heightened vigilance of the danger of a lethal attack on campus, a mentally ill college student at Virginia Tech University in 2007 murdered 33 persons, and in 2012 a mentally ill adolescent opened fire on and mortally wounded 20 children at the Sandy Hook Elementary School in Connecticut. More recently, in February 2018, a 19-year-old former student expelled from Marjory Stoneman Douglas High School in Parkland, Florida, killed 17 people in that school. There have been strident demands to develop strategies to profile potentially deadly students who may be targeting schools for deadly violence. Youths with the risk factors of a history of psychiatric illness, aggression, suicidal behavior, and/or family strife and who have access to weapons may indeed be at a higher likelihood for violence. However, less than 5% of crimes overall can be attributed to mental illness. Identifying those individuals at risk with any degree of certainty must overcome the daunting challenge of the high false-positive rate associated with predicting a rare event.

Most experts are skeptical of the wisdom of deploying armed security in elementary and high school buildings. Further, implementing zero-tolerance policies for aggressive behavior may disproportionally impact minority, disadvantaged, and special needs students who generally benefit the least from suspensions or expulsions. Alternatively, school-based interventions designed to decrease bullying and stigma, provide enhanced access to students for counseling and mental health care, expand communication among students, faculty, and parents, and eliminate or at least safeguard guns in the home all hold the promise of more effectively addressing the threat of interpersonal and self-inflicted violence.

Child Custody

Each year in the United States, there are about half the number of divorces as there are marriages. Divorce proceedings sever the marriage contract between spouses, and although children may be a focus of the case, they are not considered formal parties to the legal action. The court has the responsibility to protect the well-being of dependent children affected by divorce, which may be straightforward when the parents are in general agreement or hotly contentious when they are in battle. Child custody subsumes both legal custody, referring to the responsibility for making major decisions about health and education, and physical custody, referring to which parent is spending time with the child. Many jurisdictions favor awarding joint legal custody to both parents unless there is evidence that this would be frankly detrimental to the child's best interests. Under those circumstances, the court may grant sole legal custody to one parent, with or without time-sharing with the other parent. A determination of the best interests of the child is made by evaluating all of the factors affecting the welfare and interests of the minor child and the circumstances of that family, including, but not limited to: the demonstrated capacity of each parent to facilitate and encourage a close and continuing parent–child relationship and to determine, consider, and act upon the needs of the child as opposed to the needs or desires of the parent; the moral fitness and mental and physical health of the parents; evidence of domestic violence, sexual violence, child abuse, abandonment, or neglect; and the developmental stages and needs of the child and the demonstrated capacity of each parent to meet the child's developmental needs.

Treating psychiatrists of a parent or child in custody or visitation litigation may have important information that could influence the court's ruling. The scope and limits of confidentiality in such matters may become a difficult and contentious question. Further, the availability of the psychiatrist to write reports, testify, or advocate in these adversarial legal proceedings is fraught with conflicting ethical, legal, and therapeutic duties. Many treating psychiatrists have sought to avoid becoming entrapped in these dilemmas by limiting their documentation and recollection, though it may not be possible to predict which patient will be the source of a subpoena. Consultation with an attorney and referral to a forensic psychiatrist may be advisable for the treating psychiatrist confronted with such circumstances.

Child Abuse

Reports of suspected maltreatment, which are mandated by law for health care and school personnel, will trigger investigations by the police or a child protective agency. If probable cause for maltreatment is found, such as bruises or malnutrition, the child can be removed from the home, and the agency might petition the court for alternative placement in foster care. Allegations of sexual abuse usually result in criminal charges against a parent, family member, or nonfamilial perpetrator. As the victim of interpersonal violence, children and adolescents suffer enduring psychological injuries, which may also lead to civil court actions seeking to recover compensation for the injured child. Younger children are more vulnerable since, as a rule, they are less able to protect themselves from being exploited by adult predators.

Society and the medical profession have traveled far in the last 100 years from a time when physical child abuse was unrecognized to the current era of far greater sensitivity to multiple forms of maltreatment, including neglect, emotional and physical abuse, and sexual molestation. However, significant difficulties arise in the evaluation of allegations of sexual abuse, especially in young children. The psychiatrist examining a child about whom there is an accusation of sexual abuse must face the challenge of infusing scientific objectivity into the practical task of providing judgments regarding the validity of symptoms, their putative etiology, the harms suffered by the child, the prognosis, and what present and future treatment interventions are indicated.

58.2 Ethics in Psychiatry

LAURA WEISS ROBERTS, M.D., M.A.

Ethics is a scholarly discipline that brings a greater understanding of moral aspects of human experience and action. Psychiatry, more than any other field of medicine, concerns itself with studying and strengthening the capacities that make humans unique and that allow people to attach, learn, love, reason, feel, live with one another, and make choices. Separately and together, the fields of ethics and psychiatry examine human meaning, intention, and consequences, and both are concerned with the expanse and limits of the self in the world. Thus, by their natures, ethics and psychiatry are overlapping fields of inquiry.

With so much in common, it is perhaps surprising that the field of psychiatry enjoys more than its share of ethical controversy. Psychiatry is viewed with skepticism by society at large, and the practice of psychiatry presents a number of concerns that can be seen as ethically problematic. Even psychiatrists themselves disagree on matters of ethical importance within the profession. Long-standing ethical issues related to power and intimacy in psychodynamic–psychotherapy relationships are now joined by intriguing new ethical questions about privacy and boundaries in treatment in the modern era of telehealth and smartphone deliverables. Similarly, older dilemmas regarding the potential exploitation of vulnerable individuals in psychiatric research have now been joined by new debates regarding patient autonomy, unconscious bias, and equity in healthcare. Old controversies regarding patient confidentiality in publishing patient case reports are now joined by new uncertainties regarding privacy in technologies that use machine learning or artificial intelligence, for example, to identify individuals who are at risk of suicide based on social media activity. Novel issues pertaining to topics as widely varying as psychiatric genetics, interpersonal violence, sexuality, and global mental health disparities arise each day among the global context of a changing climate, the aftermath of a novel pandemic, and increasing demands for racial justice, highlighting the complex and evolving nature of advancing mental health care.

Learning about ethics is helpful preparation for all physicians, including psychiatrists and psychiatrists-in-training who encounter complex dilemmas in their everyday work. Physicians might begin by familiarizing themselves with relevant ethical guidelines, including those of the American Medical Association (AMA), the American Psychiatric Association (APA), and the American Academy of Child and Adolescent Psychiatry. Historical ethical codes, such as the Hippocratic Oath of the 4th-century BC and Percival’s *Medical Ethics* from the late 1800s, shed light on how standards of conduct for physicians have evolved. Psychiatrists must have a sound working knowledge of ethics resources from related areas, as well, such as professionalism, legal concerns, gender-related issues, and cultural competencies.

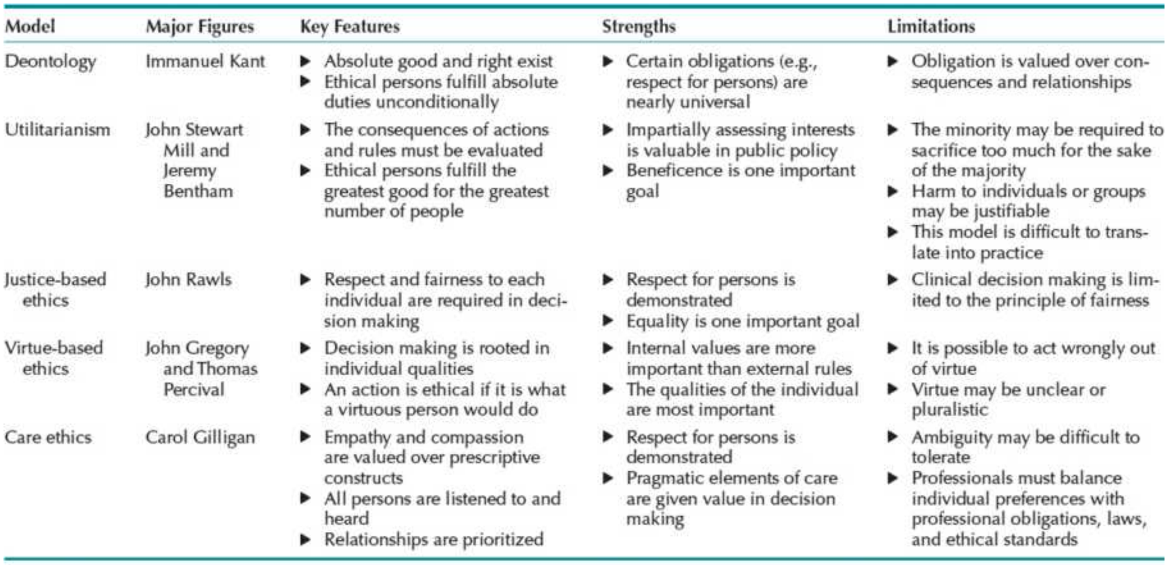
Are general codes of ethics for physicians sufficient for an understanding of the ethical requirements of psychiatrists? Should psychiatrists be held to a higher or different standard of ethics than other physicians? Many psychiatrists argue that a more complete knowledge of ethics is particularly important for mental health practitioners because of the nature of mental disorders and the impact of stigma. Others argue that greater mastery of ethics is essential because of the influence that psychiatrists may have on their patients' lives as a result of transference, the set of emotions and thoughts brought to the therapeutic relationship from the patient's prior life experience. Yet others argue that true ethics expertise, robust decision-making skills, and disciplined ethics practices are of special importance for psychiatrists because of their professional power to initiate involuntary treatment in certain situations. For all of these reasons, psychiatrists and psychiatrists-in-training will ideally possess a thorough understanding of the field of ethics, including its underpinnings and its applications.

Toward this aim, this chapter introduces the foundations of present-day ethics in psychiatry. Outlined are key bioethics principles and illustrations of approaches to identifying and resolving psychiatric ethics dilemmas.

ETHICAL SCHOOLS OF THOUGHT

Several ethical schools of thought have influenced how physicians understand ethical aspects of medical practice. Examples include the deontologic school, utilitarianism, justice-based ethics, virtue-based ethics, and care ethics.

Table 58.2–1.
Examples of Ethical Models of Thought



Model	Major Figures	Key Features	Strengths	Limitations
Deontology	Immanuel Kant	▶ Absolute good and right exist ▶ Ethical persons fulfill absolute duties unconditionally	▶ Certain obligations (e.g., respect for persons) are nearly universal	▶ Obligation is valued over consequences and relationships
Utilitarianism	John Stewart Mill and Jeremy Bentham	▶ The consequences of actions and rules must be evaluated ▶ Ethical persons fulfill the greatest good for the greatest number of people	▶ Impartially assessing interests is valuable in public policy ▶ Beneficence is one important goal	▶ The minority may be required to sacrifice too much for the sake of the majority ▶ Harm to individuals or groups may be justifiable ▶ This model is difficult to translate into practice
Justice-based ethics	John Rawls	▶ Respect and fairness to each individual are required in decision making	▶ Respect for persons is demonstrated ▶ Equality is one important goal	▶ Clinical decision making is limited to the principle of fairness
Virtue-based ethics	John Gregory and Thomas Percival	▶ Decision making is rooted in individual qualities ▶ An action is ethical if it is what a virtuous person would do	▶ Internal values are more important than external rules ▶ The qualities of the individual are most important	▶ It is possible to act wrongly out of virtue ▶ Virtue may be unclear or pluralistic
Care ethics	Carol Gilligan	▶ Empathy and compassion are valued over prescriptive constructs ▶ All persons are listened to and heard ▶ Relationships are prioritized	▶ Respect for persons is demonstrated ▶ Pragmatic elements of care are given value in decision making	▶ Ambiguity may be difficult to tolerate ▶ Professionals must balance individual preferences with professional obligations, laws, and ethical standards

These perspectives differ greatly on what constitutes the beliefs and actions of a good person. The philosophers who developed these paradigms sought to explain as much as possible with a few simple rules. Such simplicity is elegant academically, though harder to apply in real life, as Table 58.2–1 notes. Each school of thought, taken alone or taken to an extreme, may lead to conclusions that most people in a pluralistic society would find unacceptable. Nevertheless, these models provide a framework for discerning and evaluating moral issues encountered in everyday experience.

The deontologic school centered on the work of Immanuel Kant (1724 to 1804), who articulated the inherent sacredness of the individual person and the primary intention of a human being as a moral agent. He believed that certain ways of behaving are absolute from an ethical perspective, irrespective of consequences. Kant articulated a rule called the “categorical imperative” guiding all moral behavior. His first formulation of the categorical imperative was that a person should “act only on that maxim through which you can at the same time will that it should become a universal law.” For example, in deciding whether to lie or steal or kill, individuals should think about whether they want others to engage universally in these behaviors. Kant’s second formulation of the categorical imperative was to “act in such a way that you always treat humanity, whether in your own person or in the person of any other, never simply as a means, but always at the same time as an end.” In other words, it is unethical to use another person solely as an object to obtain a goal without concern for the effect of one’s actions on the person. Moral value, in Kant’s system, relates to respect, rationality, and duty in relation to the moral agent.

The utilitarian school of thought originated with Jeremy Bentham (1748 to 1832) and John Stuart Mill (1806 to 1873) in 19th-century England. They argued that the value of an act should be judged solely on its effect or consequences. Acts are ethically right, in this view, if their effect is to produce the greatest good for the greatest number of people. Acts are not right or wrong in and of themselves, according to act-utilitarians. Lying, stealing, and killing are not inherently wrong, for example. In this school, the ends justify the means. Rule-utilitarianism moves beyond act-utilitarianism to suggest that good individuals will undertake decisions guided by rules that—if followed by all people—would bring about the greatest good for the greatest number of individuals. In this formulation, there is more “forgiveness” for decisions with unpredictably negative outcomes. Rule-utilitarianism does not address the role of the intentions of individual moral agents, nor does it answer the question of what is “good.”

More recently, in contrast with utilitarianism, John Rawls (1921 to 2002) developed a school of thought drawing from his concept of justice. It followed upon strengths of Kant’s deontologic approach in that it highly valued the individual as a moral agent. Rawls supported the rights of the individual as a matter of fairness. He gave primacy to the intrinsic worth of each person rather than to a metric that assessed the greatest utility for the group as a whole. He stated, “Each person possesses an inviolability founded on justice that even the welfare of society as a whole cannot override.” Rawls asserted that in deciding what to do and what rules and systems to establish, people should place themselves behind a “veil of ignorance” and assume that they do not know who they are in the system. For example, in deciding what welfare benefits a society should offer and the amount of taxes to impose on the rich, people should assume that they do not know whether they will be rich or poor. In deciding what authority doctors have over patients, people should assume that they do not know whether they will be in the role of the doctor or in the role of the patient. Rawls’ approach, as with that of Kant, does not rely on the consequences of actions but, rather, their primary intent.

Virtue-based theory has contributed greatly to the ethical framework of medicine and the key concepts of professionalism. John Gregory (1724 to 1773) was a Scottish physician–ethicist, and Thomas Percival (1740 to 1804) was an English physician–ethicist. Their work, taken together, created the foundation for the modern ethical concept of medicine as a profession. Concerned about exploitative, self-interested, and entrepreneurial practices of physicians at the time, they articulated the virtues of scientific and clinical competence, dedication to the interests of the patient, and service to the public through ensuring the skills of peers and students or apprentices. Gregory described the moral qualities of an astute and compassionate physician as follows:

> The chief of these is humanity; that sensibility of heart which makes us feel for the distresses of our fellow-creatures, and which, of consequence, incites us in the most powerful manner to relieve them. Sympathy produces an anxious attention to a thousand little circumstances that may tend to relieve the patient; an attention which money can never purchase. . . If the physician possesses gentleness of manners, and a compassionate heart, and what Shakespeare so emphatically calls 'the milk of human kindness,' the patient feels his approach like that of a guardian angel ministering to his relief: while every visit of a physician who is unfeeling, and rough in his manners, makes his heart sink within him. (Gregory, John. *Lectures on the Duties and Qualifications of a Physician*. Carey & Sons; 1817:22,23.)

Gregory and Percival individually emphasized the virtues of the honorable physician as demonstrating self-sacrifice and self-effacement and as seeking at all times to advance the field of medicine, not for financial gain but the benefit of others in society. The modern notion of integrity derives from this line of thought, and the work of Gregory and Percival continues to inform the discussion of conflicts of interest and how they may be avoided or resolved.

Carol Gilligan (born 1936) developed care ethics as a skeptical response to the history of ethical thought, in which concepts of "moral development" elevated predominately by empowered white men were naturalized while historically marginalized voices were excluded, amounting to arbitrary moral indifference. While deontologic, utilitarian, and justice- and virtue-based ethics primarily employ prescriptive ethical constructs, care ethics emphasizes modes of cognition, such as empathy and compassion, and pragmatic elements of care, such as attentiveness, responsiveness, and interdependence, that require epistemic openness, humility, and tolerance of ambiguity. Care ethics affirms a decision-making process in which all individuals are valued according to these ideals.

These schools of thought have been highly influential in present-day principles of ethics that the AMA and APA advance. Other schools of thought exist in the United States and throughout the world, with rich and long-standing traditions and different implications for current practice. From legal and ethical points of view, physicians engaging in professional activities in the United States are held to the AMA and APA codes of ethics and standards.

BASIC ETHICAL PRINCIPLES

The modern field of biomedical ethics takes a primarily principle-based approach. In their influential text *Principles of Biomedical Ethics,* Beauchamp and Childress defined the most critical principles to be autonomy, beneficence, nonmaleficence, and justice. The Belmont Report on human research ethics elevated the concept of respect for persons, and ethics scholarship has emphasized the principle of respect for the law. Other principles, such as compassion, confidentiality, fidelity, integrity, and veracity, are also central to the practice of psychiatry. See Table 58.2–2. Ethical analyses examine the interplay of these principles and seek to identify and resolve when ethical principles are in conflict.

APPROACHING ETHICAL DILEMMAS

Ethical dilemmas do not typically emerge in simple situations of doing good versus doing bad. In such situations, there is no dilemma. Indeed, ethical dilemmas occur when two seemingly good things are at stake. Consider the example of a psychiatrist who receives a request from a worried and loving mother to provide information about issues arising in her son’s therapy sessions. The son has a good relationship with his mother but has been bullied at school, feels embarrassed, and does not want his parents to know what is bothering him. For the psychiatrist, the good of responding empathically and with accurate information to the distressed mother competes with the good of protecting the fragile patient alliance with the son. Dilemmas often come when two or more of the basic bioethics principles are in conflict or cannot be completely fulfilled given the circumstances of a particular situation.

Table 58.2–2.
Examples of Biomedical Ethics Principles

Autonomy	The notion of self-rule; the capacity to make authentic decisions related to one's body and mind.
Beneficence	Doing good; the commitment to seek to bring about benefit.
Compassion	Deep regard for the experiences and suffering of others.
Confidentiality	A legal privilege associated with the right of privacy; the obligation not to disclose information obtained from a patient or observed or gathered in caring for a patient.
Fidelity	"Faithfulness" or loyalty to ethical ideals.
Integrity	The notion of being whole or complete; the capacity to adhere wholly to the principles of the profession.
Distributive justice	Equitable distribution of benefits and burdens in society.
Nonmaleficence	Avoiding harm or injury to others.
Respect for the law	The obligation to adhere to the law.
Respect for persons	Fundamental regard for the dignity, sacredness, and value of the individual.
Veracity	"Honesty," involving the positive duty to tell the truth and the negative duty to avoid deception.

Recognizing Ethical Issues and Tensions

The ability to identify ethical issues and tensions present in the patient care situation is thus the first and most basic of the ethics skills important to the sound clinical practice of psychiatry. Indeed, it is increasingly appreciated that every aspect of clinical care can have ethical significance. The judgment of a clinician that a patient's characteristics, symptoms, or challenges warrant a psychiatric diagnosis has ethical meaning. Moreover, the observation that individuals who belong to underrepresented minority groups are more likely to receive more serious and more stigmatized clinical diagnoses, such as schizophrenia, than individuals who belong to majority groups– despite having the same symptom profiles and clinical histories– reveals the role of bias and potential discrimination in assessment and diagnostic procedures.

Recognizing the ethical features of a patient’s case requires sensitivity, and this capacity is enhanced by knowledge of ethical principles and how they may come into conflict.

Seeing how ethical principles may compete or collide is informative and can help practitioners to discern a path forward. For instance, consider the case of a newly diagnosed cancer patient who, overwhelmed and fearful, attempts suicide by overdose. She requests aid in dying from her oncologist, who also feels overwhelmed and fearful because of the patient’s reaction, and refers the patient for a psychiatric evaluation. The psychiatrist learns that the patient’s mother died from cancer and that she was her mother’s only caregiver over the long and difficult course of her illness. The psychiatrist finds that the patient likely had a pre-existing depression before learning of her cancer diagnosis. The patient is decisionally capable, despite her distress, and the psychiatrist feels great empathy for the patient. In this example, many principles are in play, and several are in tension: most clearly, honoring the patient’s wish to die (autonomy) conflicts with the physician’s responsibility to avoid harm (nonmaleficence). A superficial analysis would suggest that the patient’s right, especially in an autonomy-oriented society, would trump all other considerations.

Sound standards for clinical and ethical care are those that are informed by the full set of ethical principles that govern medicine. By recognizing the two principles that are in opposition—in this case, autonomy and nonmaleficence—and considering the other principles at play in the situation, the clinician begins to see additional options for intervention that align with standards of medicine. In this case, identifying ways of reducing the patient’s physical and psychological suffering, treating her pre-existing condition, providing accurate information about the nature of her condition and potential treatments, and adhering to state legislation regarding assisted suicide all may contribute to an improved physical and mental health outcome for this patient. Ideally, clinical care and ethical reflection work together, as illustrated in this case.

The disciplined exercise of identifying ethically salient concerns in a clinical situation and framing and exploring the relevant bioethics principles can help open up the thinking of the clinician. Reflecting on related areas that influence ethical facets of the case, such as considerations regarding the law, the patient’s background or identity, and the patient’s culture is also valuable. These efforts, taken together, represent an important ethical skill and the initial step in clarifying ethically sound strategies for optimal patient care.

Gathering Additional Information and Expertise

Ethical questions sometimes arise in a clinical situation when there is simply too little information or when clinicians are working at the boundary of their experience or scope of practice. In such situations, additional information or broadened and deepened expertise may lead to a ready resolution of the problems at hand. Data or expert guidance could come from the patient’s prior medical records or clinical practice and ethics guidelines. In addition, speaking with an experienced supervisor, seeking advice from a colleague with specialized expertise, requesting ethics or legal consultation, and/or reviewing supplemental clinical data from outside sources may help.

Consultation-liaison psychiatrists see the value of additional data-gathering and consultation as resolving apparent ethical issues frequently in their work. Psychiatric consultation services have long fulfilled an important ethical function in most hospitals. For example, if a patient is declining potentially life-saving care for what appears to be an irrational reason and is demanding to return home against medical advice, a psychiatric evaluation may reveal an underlying condition, such as an addiction, delirium, early dementia, or poor pain control, interfering with the patient’s decision making. Once this underlying condition is treated and the symptom burden is lessened, the patient’s decisional capacities may improve, leading to what appears to be a more rational decision to the caregiving team. If the patient is not experiencing a threat to their decisional capacity, it is important to explore the patient’s values, background, and reasons for making a decision that contrasts with the medical recommendation. Cultural and religious preferences, fears based on past experiences, implicit bias, or issues related to family stresses may be influencing the decision. Seeking additional background information to evaluate these factors may be very helpful in developing health-preserving strategies for this patient, such as consulting a religious leader, inviting emotional support from a family member or counselor, or identifying appropriate social service resources. In all of this, the caregiving team is wise also to obtain consultation from the legal service of the hospital. Information on the role of state or federal law in the case will help the physicians to determine whether temporary or long-term guardianship may be appropriate to pursue.

Thus, in approaching an ethically complex clinical situation, recognizing the ethical dimensions of a patient's care and then seeking additional information or expertise are the two initial steps to take in resolving dilemmas and developing ethically astute treatment plans.

Identifying Risky Situations and Arranging for Appropriate Safeguards

Many situations in patient care present predictable ethical challenges, and with experience, astute clinicians begin to anticipate when these ethically risky situations are likely to occur. A clear illustration is when a patient is impulsive, and the caregiving team must ensure the safety of the patient and others, for example, family members or the clinic staff. The clinician may be tempted to make choices that differ from usual clinical practices because of the situational threat. When the patient is a celebrity or an influential person, other ethical risks can enter into the clinical picture. Staff members may be tempted to review the patient's electronic medical record, and caregiving physicians may begin to change their usual clinical practice, consciously or not, in order to please or garner favor with the special patient. A very different example is when there is a need to report child abuse or neglect. In this case, the psychiatrist may feel emotionally conflicted, wanting to abide by the law but feeling worried about the impact of the intervention on the therapeutic alliance with the family or about the impact of the investigation on the child. When entrusted with the care of vulnerable individuals, such as trauma survivors, children, or extremely ill patients, psychiatrists will recognize numerous ethical risks that may arise.

Ethical dilemmas signal the need for additional safeguards in order to ensure that an appropriate standard of care is upheld. Additional safeguards may include incorporating a broader health care team, introducing alternative decision-makers for vulnerable patients who lack decision-making capacity or obtaining permission from the patient to engage the family more fully. When a psychiatrist routinely works with high-risk patients, the clinical setting itself must have more safeguards, such as physical safety training for clinical staff. A geriatric psychiatrist who works with many individuals with advanced dementia may need to have a close working relationship with other clinicians, legal advocates, and the court in order to facilitate optimal patient care. In sum, heightened safeguards help address the ethical risk that is associated with psychiatric practice in all settings. When such risk is predictable because of the context or the patient population, ethically astute psychiatrists will build safeguards into their routine practices for the good of the patients and the caregiving team.

Working Within One’s Scope of Practice and Engaging in Continuous Learning

Working within one’s scope of clinical competence is considered ethically important because of the risk of doing harm when practicing with insufficient expertise to care for a patient properly. If physicians are confronted with patient care situations that are outside of their scope of competence, then referral or, at the very least, consultation and supervision are appropriate. Sometimes physicians practice in settings where referral is not feasible. In rural settings, for example, telehealth services may bring additional expertise to the care of the patient. In training settings, where early-career physicians may lack expertise, close supervision helps to ensure an appropriate standard of care. In emergency situations, clinicians are expected to do their best and not to abandon the patient in extreme need.

Related to the ethical obligation to work within one’s areas of competence is the responsibility to continue to learn. This imperative relates to the fundamental concepts of serving the best interest of the patient and avoiding harm in clinical care. Remaining aware of advances in one’s field of practice and domains of competence is critical to optimal patient care and ensures that one’s practice remains within community standards.

Reflecting on One’s Values and Perspectives

Psychiatrists are taught to pay close attention to their responses to a patient, including how they respond to a patient’s appearance, emotions, and personal story. Implicit bias greatly shapes interpersonal interactions in everyday life and in clinical care. Awareness of potential sources of bias and of countertransference (the set of emotions and thoughts that the psychiatrist brings to the therapeutic relationship from prior experiences) is valuable in clinical care and provides insights into the ethical dimensions of a patient’s care. Indeed, to conduct ethically sound patient care, psychiatrists must be able to see how their experiences, attitudes, and feelings influence their perceptions of the ethical aspects of a clinical situation. Awareness of one’s reactions may help prevent ethical blind spots and even breaches of ethical conduct. When a psychiatrist finds a patient very attractive or when a patient makes the psychiatrist very uncomfortable or angry, these emotional cues should be seen as clinical and ethical signs that require acknowledgment, clinical interpretation, and a therapeutic response.

Medical professionals are just as susceptible to biased thinking as the general population. Implicit and explicit biases held by health professionals perpetuate health disparities and nonequitable systems of care. A commitment to addressing discrimination and identify and eliminate structural bias through clinician training and other methods is increasingly viewed as a professional value and necessary to uphold ethical principles.

Ideally, team-based care and teaching settings will create opportunities to consider how different team members or supervisors, and trainees view the ethical issues present in a patient care situation. Astute team leaders will facilitate explicit discussion of these issues and guide their colleagues in defining the conflicting ethical principles. Clarifying differences in the points of view of team members may prevent later misunderstandings. Team leaders can demonstrate the importance of speaking with the patient, gathering additional data, working within one’s scope, introducing specialized expertise, and building in appropriate safeguards.

DECISION-MAKING STRATEGIES

Jonsen, Siegler, and Winslade created a four-part model for clinical decision making that many health care settings have adopted. The four elements to consider when making a decision include (1) clinical indications, (2) patient preferences, (3) quality of life, and (4) socioeconomic or external factors. In this model, clinical indications have the greatest weight on decision making. Clinical indications refer to the physician’s obligation to diagnose a patient’s condition carefully, to inform and educate the patient about the illness process, to consider the available treatment options in light of appropriate standards of care, to make therapeutic recommendations that adhere to these standards, and to ensure that treatments are provided competently and fulfilled properly in partnership with the patient.

The second element of this decision-making model, patient preferences, is grounded in the principles of respect for persons and autonomy. Once the physician presents the patient with recommendations based on what is clinically indicated, the physician elicits the preferences of the patient. In the practice of psychiatry, the nature of mental disorders may interfere with patients’ decisional capacity, voluntarism, or ability to identify or express their preferences. The ethically astute psychiatrist will thoroughly evaluate decisional capacity, keeping in mind that this capacity may change with time and under certain circumstances. When a patient is unable to provide informed consent, appropriate decision-making safeguards, such as an alternative decision-maker, may be put in place in accordance with state law.

Quality of life is the third element in the Jonsen, Siegler, and Winslade model, referring to the sense of personal satisfaction individuals express and/or experience with regard to their physical, mental, and social situations. In assessing quality of life, physicians must directly engage with patients regarding their values and points of view. The physician must not make assumptions about what represents a good life for the patient. Clinical indications and patient preferences are weighted more heavily than quality of life in the decision-making model because, when overweighted or incorrectly assessed, quality of life could be used to justify decisions that do not meet current ethical standards in society.

The fourth element in this clinical decision-making model entails socioeconomic or external factors. These factors are diverse and include the interests of society, the role of family members, cultural factors, and costs and limitations in access to care. This element is last primarily because of the obligations of beneficence. The United States defines denying a patient life-saving treatment in an emergency on the basis of ability to pay as unethical and illegal, for example. In less acute situations, however, a discussion with patients about the costs of care and how these costs may affect their choices of treatment is important and ethically acceptable.

EXAMPLES OF ETHICAL PRACTICE STANDARDS IN PSYCHIATRY

Several texts and resource documents provide comprehensive overviews of ethical practice standards in psychiatric practice. Key concepts related to several ethical practice standards for psychiatry are briefly outlined below and draw upon the schools of thought, biomedical ethics principles, and the four-part ethical decision-making model described in this chapter.

The Therapeutic Relationship and Professional Boundaries

The therapeutic relationship presupposes that the physician is worthy of the patient's trust. The physician's expertise and the physician's intention to do good, avoid harm, and place the patient's best interest above all other interests are the basis of that trust. Professional boundaries are behaviors that align with these fundamental commitments to serve the wellbeing of the patient.

Interactions with patients fulfill or gratify the interests of the physician rather than the interests of the patient can fracture or destabilize the foundation of trust. One example is the ethical problem of intimate relationships arising between physicians and patients. The APA is explicit in its direction that psychiatrists must not engage in sexual relations with patients, including former patients. Such intimacies are inherently exploitative; they interfere with therapy, risk harm to the patient, and undermine confidence in the profession, thereby damaging the ability of others to benefit from psychiatric care. The profession of psychiatry sees sexual contact during therapy or ending therapy in order to start a relationship as indefensible.

Some have argued that the power differential between a former therapist and patient is the primary reason to forbid relationships between them. Many relationships, however, have power differentials because of the different earning capabilities of the partners, different levels of educational achievement, or a society that gives more power to one gender, one class, or one ethnicity over another. The reason to bar sexual relationships between psychiatrists and present and former patients is more complex than that. The prohibition protects patients from being lured into a relationship that the patient would not otherwise desire because of a genuine need for treatment. The prohibition also helps to ensure that the psychiatrist stays focused on the patient's wellbeing. Self-effacement is an important virtue that asks physicians to put away their own needs or wishes for the sake of the patient’s health and wellbeing. The modest and self-effacing psychiatrist is willing to forgo relationships with patients outside of standard treatment. The Exploitation Index developed by Epstein helps therapists to identify potentially exploitative practices in the care of their patients.

Therapeutic boundary violations are behaviors that subordinate the interests of the patient to the interests of the physician and are not compatible with the ethical practice of psychiatry. These violations are, by definition, exploitative, although they need not be sexual or romantic. Boundary violations include seeing patients outside of normal office hours or in nonclinical locations, engaging in social or business relationships with patients, accepting gifts from patients, and making nonsexual physical contact with patients. “Friending” or following a patient on social media or completing a Google search for a patient’s name are generally considered boundary violations because these actions are likely to serve the interests of the therapist rather than the best interests of the patient. These types of violations carry the potential to take advantage of the patient or to harm the treatment relationship and should therefore be avoided.

Therapeutic boundary crossings are behaviors that are intended to serve the interests of the patient but differ from usual ethical practices. A psychiatrist disclosing personal information to build rapport with a distant and troubled patient or accepting a small handmade gift at the holidays to demonstrate respect for a patient’s culture are two examples of boundary crossings.

Traditional views of the boundaries in the therapeutic relationship derive from reflection on long-term, dynamically oriented psychotherapy relationships, typically occurring in urban contexts. Novel questions arise when considering other roles, interventions, and settings. For example, is a child psychiatrist caring for impoverished and traumatized youth in a culturally unique community held to the same expectations as a therapist caring for an older, successful businessperson in a major metropolitan location? Are psychiatrists who see patients once in an emergency department held to the same standard of personal–professional role separation as their ambulatory clinic counterparts? Does a psychiatrist who is consulted about the suitability of a patient with Parkinson disease for neurosurgical intervention establish a therapeutic relationship with the patient in the same manner as with a patient needing treatment for depression? Intuitively, these situations require more nuanced responses than strict rules or inflexible codes of ethics. For this reason, medical ethics is understood to evolve by its very nature. This fact does not permit psychiatrists to deviate from expected standards but, rather, permits psychiatrists to apply standards (and, more importantly, their underlying intent) to novel situations.

Confidentiality

The importance of confidentiality in tending to illness dates back to Hippocrates, who said, “What I may see or hear in the course of the treatment or even outside of the treatment in regard to the life of men, which on no account one must spread abroad, I will keep to myself, holding such things.” Confidentiality refers to the physician’s duty to not release information learned in the course of treatment. Salient information may relate to disclosures by the patient, observations of the physician, or laboratory findings, or notes from prior treatment in the medical record. Protection of patient confidentiality fosters the therapeutic alliance and is a prerequisite for patients to be willing to speak freely and openly with their doctors. Table 58.2–3 notes illustrations of optimal practices for protecting confidentiality in psychiatric practice.

Table 58.2–3.

Examples of Optimal Approaches to Confidentiality in Clinical Practice

- Provide accurate information to patients about the realities of confidentiality in the clinical setting.
- When appropriate, remind patients that the purpose of the medical record is to be shared as a way of providing optimal care by a team of health professionals.
- Openly discuss with patients the legal limitations of confidentiality and avoid assuring patients that their disclosures will be “completely” confidential.
- Do not speak to others or, if working in a team-based care setting, avoid talking with others beyond the health care team, about patients’ care without explicit, written permission to do so.
- Actively work within organizations and professional societies to develop state-of-the-art confidentiality safeguards as science, clinical care, health policy, the law, and health care systems evolve.
- Seek consultation and expert guidance when confidentiality safeguard questions arise.
- Model best practices in confidentiality to colleagues, team members, and trainees.

Psychiatric records, including even the identification of a person as a patient, must be protected with particular diligence. A psychiatrist may release confidential information only with the authorization of the patient or when compelled by law. Even when patients have given permission for their personal information to be used, safeguards are still needed. It is important to disclose only that information that is truly necessary for the situation at hand. In teaching and research, one should not unnecessarily release patients’ names or identifiable information. Presenters of patient material in ward rounds and case conferences should remind attendees not to repeat what they hear. Confidentiality and the ethical obligation to withhold information endure even after a patient’s death.

In an era of electronic health records, digitized medical information, and a push toward national health identifiers, whether, to what degree, and how special privacy protections for mental health treatment will continue to be guarded remains unclear. As patients are increasingly able to access their entire medical record, new issues come to light about the extent to which mental health records may receive additional or special safeguards. Although “break the glass” protocols for accessing mental health records are now common, such protocols still allow many different providers access. Mental health providers must remain aware of who has access to the documentation in a patient’s electronic medical record. Transparency of health records has been adopted in many countries. Psychiatrists thus have a responsibility to consider the mental health impact that patients may experience if they access their health records. Psychiatrists may elect to review health record documentation with their patients.

New ethical questions arise every day regarding confidentiality in novel forms of treatment, whether medical or psychosocial. For instance, what are appropriate privacy protections for psychotherapy occurring by telephone, video, Internet, email, or texting? Should health data collected via wellness applications and passive symptom tracking be awarded the same protections and safeguards as data collected in a hospital or clinic setting? How will innovators in clinical research and genetics protect the personal information of specific individuals whose biomarkers, taken together, represent a unique biologic signature?

Informed Consent

Informed consent is an ethical and legal standard that exemplifies the principle of respect for persons and seeks to bring the principle of autonomy to life in clinical medicine. Informed consent is the idea that capable and knowledgeable individuals may freely choose a course of action pertaining to their health. Informed consent can involve accepting a recommended treatment or choosing an alternative, including no treatment (i.e., informed refusal).

Informed consent involves three components: information-sharing, decisional capacity, and voluntarism. With respect to information-sharing, physicians should provide patients accurate and balanced information regarding (1) the nature of their illness or condition; (2) the need for intervention; (3) the anticipated risks or benefits and their relative likelihood, including rare but very serious risks; (4) appropriate alternatives and their attendant risks and benefits; and (5) future consequences of the different choices, to the extent possible. Physicians should offer this information at the level and in a language that the patient understands and, to the extent possible, in an unpressured environment.

Physicians should build opportunities to clarify points of information and to correct misimpressions into the conversation. Individuals who cannot provide consent must receive information at the level at which they can understand it, and physicians should seek the individuals' acceptance when possible. See Table 58.2–4.

Grisso and Appelbaum characterized decisional capacity as having four subcapacities. The first is the physical and mental ability to communicate. This subcapacity does not refer to the ability to speak a particular language but, rather, the ability to express—including through eye blinks or hand signals—a choice. The second subcapacity is the ability to understand relevant factual information. The third subcapacity is the ability to reason, that is, to weigh the different factors and risks and to think through the choice at hand in an objective and flexible manner. The fourth subcapacity is the ability to appreciate the meaning of the decision and to evaluate the choices in the context of one's life. This capacity is close to the concept of insight, which usually refers to patients' ability to understand the nature and impact of their illness. The capacities should be viewed as a continuum, not simply as present or absent.

Table 58.2–4.
Examples of Optimal Approaches to Informed Consent in Clinical Practice

---

- Provide accurate information regarding the nature of the illness and the need for clinical intervention; anticipated risks and benefits of the proposed intervention, including rare but serious risks; alternatives to the proposed treatment and their likely outcomes, including no intervention.
- Avoid using overly complicated language and overwhelming patients with too much technical information.
- Be attentive to patients' comfort, communication style, and interpersonal cues.
- Invite patients to ask questions and double-check their understanding of what was explained.
- Provide additional information if requested by patients.
- Use translators when appropriate and, if desired by patients, include family members in the information-sharing session(s).
- Supplement the information-sharing dialogue with written materials as appropriate.
- Evaluate each of the four components of decisional capacity: capacity to communicate, capacity to understand, capacity to reason, and capacity to appreciate.
- If symptoms or stressors interfere with optimal decision making, seek to ameliorate patients' discomfort to help support their ability to approach the decision process.
- Invite patients to express their preferences.
- Explore the reasons and hopes behind these preferences.
- Provide emotional reassurance and eliminate, to the extent possible, coercive pressures that patients may be feeling.
- Clarify patients' values and patterns of past personal decisions.
- Create a context of nonjudgmental support and open and ongoing communication with patients.

Many psychiatric conditions erode the cognitive strengths that underpin decisional capacities. Patients with severe and persistent mental illness may suffer episodic, fluctuating, or progressive impairments of decisional capacity. Ideally, the informed consent process consists of repeated opportunities over time to gather relevant clinical information and to discuss and clarify patients' values, preferences, informational needs, decisional abilities, and decision-making processes. Engaging with consent in a manner that is ongoing and continuous enhances patients' abilities to express greater autonomy, voluntarism, and informed decision making, and more deeply and honestly fulfills the ethical obligations of the physician.

Voluntarism is the capacity that relates to one's ability to act freely, in the absence of coercion, in expressing one's authentic wishes. “Deliberateness, purposefulness of intent, clarity, genuineness, and coherence with prior life decisions” are key elements of the capacity for voluntarism.

Roberts has conceptualized voluntarism as having four cardinal dimensions: (1) developmental factors, (2) illness-related factors, (3) psychological issues and cultural and religious values, and (4) external features and pressures. These four dimensions help to bring additional specificity and nuance to the discussion of autonomy. For example, the voluntariness of an adolescent is understood in clinical practice and in law as less than that of a legal adult except in certain circumstances. Some health conditions render affected individuals as less able to identify (e.g., in relation to alexithymia), to voice (e.g., in relation to mutism), or to enact (e.g., in relation to avolition, amotivation) their personal preferences or decisions. In some cultures, individuals are not encouraged to hold their own distinct and personal choices but instead to subordinate any individual needs to a larger group. And, finally, in some settings, such as institutional, clinical, or legal contexts, individuals may have diminished freedoms or subjectively experience themselves as having diminished freedoms, which affects individual voluntarism.

Informed consent standards are more rigorous for high-risk decisions than for other decisions. This concept is referred to as the “sliding scale” for informed consent. When patients make a choice that may endanger them (e.g., choosing one form of chemotherapy over another), the standard for decisional capacity is higher than when they make a choice that poses minimal or virtually no risk (e.g., having their blood pressure taken). Because declining recommended treatment usually entails heightened risk, the standard for informed refusal also is higher. Physicians must give extra care in providing information and counseling patients regarding alternatives and in verifying decisional and voluntarism capacity if a decision under consideration, whether accepting or refusing an intervention, is high risk.

When an individual is not capable of informed consent or refusal, others who are legally authorized may make decisions for the patient. In some cases, the patient may designate the alternative decision-maker. For young children, a parent or guardian may make the decision. At times, a formal legal process must identify a suitable decision-maker. State laws differ in how to identify decision-makers and what direction decision-makers receive, such as whether to make the decision that appears to be in the best interests of the patient or the decision that most closely resembles what the patient would choose if it were possible (i.e., “best interests” vs. “substituted judgment” approaches).

Overlapping Roles and Conflicts of Interest

Differing and overlapping roles are common for professionals who serve society as clinicians and also as teachers, consultants, administrators, and public policy experts. Having more than one role generates ethical questions and often ethical tensions because the duties of each role, by definition, do not align perfectly. (Having more than one role creates dual role, or dual agency, problems.) When roles receive compensation from different sources, issues also arise in relation to competing interests and divided loyalties. Many controversies related to conflicts of interest have become a focus of governmental policy and media reports. Ethically, conflicts of interest matter greatly in that patient needs may be subordinated to the interests of physicians who are motivated by greed rather than serving patient wellbeing. Conflicts of interest occurring at multiple levels—among individual physicians, institutions, and systems of care and research—have eroded public trust in the medical profession.

To illustrate, dual agency conflicts may arise for psychiatrists who work in the military, occupational health programs, or correctional settings. For example, psychiatrists may be called on to use their expertise to make a recommendation on a patient’s fitness for duty, competency to stand trial, or disability. As a result of the evaluation, the patient ultimately may be returned to front-line military or police work or to prison or may receive (or not) financial compensation. The ethical question of what decision serves the best interests of the patient becomes moot in these situations in which the other duties of the psychiatrist, such as protecting the public, become predominant. Particularly vexing dilemmas arise in the correctional setting, where psychiatrists may be called on to treat patients against their will when treatment would improve their disorder at the expense of their interests. Psychiatrists may not ethically force treatment on patients to make them competent to be executed. The issue is less clear concerning making patients better able to stand trial when doing so might lead them to spend more time in jail. Honesty, transparency, objectivity, and rigor—always important—are especially salient in the context of dual agency. The key issue to ethical behavior in such situations is to provide accurate information about the nature of the evaluation process, including information about the physician's responsibilities beyond those to the patient and about how usual expectations regarding patient confidentiality are not in force. Before the examination begins, physicians must notify the individuals explicitly about how they will disclose or report the information and conclusions from the evaluation.

Physicians can manage many conflicting roles and conflicts of interest in professional roles through the conscientious use of safeguards such as role separation, recusal, financial limits, responsibility limits, and additional supervision or oversight. Because public trust is at stake in issues of conflict of interest, broad dialogue and scrupulous attention to emerging guidelines and principles are very important for all fields of medicine, including psychiatry. Integrity—namely, intending good, being transparent, adhering to professional standards, and simply behaving in a manner that is worthy of trust—is key. Psychiatrists, moreover, should play an active role in educating the public on the value of professionals participating in broad activities in society, such as research, education, administration, and policymaking, in order to bring the greatest positive value of medical expertise to broader society.

Psychiatric Opinions

In 1964, Barry Goldwater was the Republican candidate for president of the United States. *Fact* magazine sent a questionnaire to U.S. psychiatrists asking whether Goldwater was psychologically fit to serve as president. Despite any direct knowledge of Goldwater derived from an in-person interview, approximately half of the psychiatrists who responded to the survey said he was not fit to serve in the role. The magazine then published an article proclaiming, "1189 Psychiatrists Say Goldwater is Psychologically Unfit to be President." In response, the APA asserted that it is unethical to render psychiatric judgments about a person in the media.

It is clearly unethical for psychiatrists to render a definitive psychiatric opinion about someone for whom they have only very limited information or only a biased source of information, such as the media. The practice appears nevertheless to be quite common. Invoking one's expertise as a psychiatrist without full knowledge of a patient is misleading and inappropriate. It is, however, ethical to render an opinion about someone one has not evaluated if one has an adequate source of unbiased information and is prudent in stating the limits of one's knowledge. In fact, psychiatrists commonly render opinions about people they have never met. When senior psychiatrists supervise residents or other mental health practitioners, they render opinions and make suggestions on treatment, although they may not have met the person in question. Psychiatrists are sometimes asked to render an opinion on testamentary capacity—whether someone who is now deceased had the capacity to make an informed decision and whether the person was subject to undue influence. Moreover, esteemed psychiatrists have studied political leaders and historical figures and thereby advanced the understanding of history and human behavior. Similarly, it is ethical for psychiatrists to reanalyze the data of a neutral forensic evaluator and make conclusions about parties they have not interviewed if there is adequate information in the neutral forensic evaluator's report to do so.

Thus, the ethics of rendering an opinion about a person whom one has not examined depends on several factors. Key issues include the purpose of rendering the opinion, the quality of information, and the reason for not interviewing the person.

Responsibilities to Third Parties

Several court rulings have stated that psychiatrists have a responsibility to third parties. These concerns are more properly forensic in nature but are relevant to good ethical practices because of the ethical notion of respect for the law. Court rulings create case law, not ethics. Nevertheless, case law leads to new expectations and indicates society's view of professional responsibilities. Legal rulings also have value because they point ethicists' attention to issues that need deeper consideration. In the original and subsequent *Tarasoff* decisions, for example, the courts upheld the position that psychiatrists must act overtly to protect the community. Courts have held psychiatrists liable when their patients, or former patients, have injured or killed people with guns or by reckless driving (e.g., 1983 *Jablonski v. US;* 1988 *Naidu v. Laird;* 1980 *Lipari v. Sears, Roebuck and Co.;* 1983 *Petersen v. Washington*). Subsequent legislative rulings have limited psychiatrists' liability in such matters. Psychiatrists who provide incorrect information place themselves at risk if such action harms the interests of a third party (e.g., *Molien v. Kaiser Foundation Hospitals* and *Ramona v. Isabella*). When clinicians give direct suggestions that affect third parties (such as the advice to get a divorce) rather than helping patients evaluate their choices in the context of their lives, clinicians leave themselves liable for the consequences. The liability is increased if they become directly involved by participating in a confrontation with the third party.

Self-Care and Impairment

Stress, distress, and illness can be occupational hazards of the work of psychiatrists and other physicians. Beyond these concerns, general mental health and wellbeing concerns are increasingly prevalent among medical students, residents, and practicing clinicians, as is the phenomenon of professional "burnout." Burnout has been defined as a syndrome tied to chronic workplace stress involving emotional exhaustion, depersonalization, and lack of personal accomplishment. Extreme stress can cause significant mental health concerns and challenge personal relationships. Health care professionals are also at risk for making errors in patient care when under extreme stress. For these reasons, the imperative to engage in self-care has arisen as a key ethical commitment of health professionals. Individuals who identify as nonmajority, who have greater financial debt, or who are experiencing health problems may also experience greater stress in their professional work. In all of these situations, there can be a "double bind" in which the clinician is responsible for "self-care," and yet the factors that lead to burnout are outside of the control of the individual. For these reasons, self-care alone is not the answer for eliminating stress, distress, and related illness conditions. Greater equity, flexibility, and support in the workplace and in the broader culture of medicine have been identified as constructive approaches that can help diminish the emergence and perpetuation of burnout among health professionals.

As noted by the AMA's *Principles of Medical Ethics*, professionals have a duty to report colleague misconduct and impairment. Misconduct is defined as professional acts that violate ethical standards, while impairment is the inability to practice medicine due to physical or mental illness or deterioration or the excessive use of addictive substances, such as alcohol. Both may result in harm toward patients, colleagues, or others and should be guarded against, in keeping with the ethical principle of nonmaleficence.

A perceived lapse in professionalism may or may not constitute misconduct, depending on whether or not an ethical standard is violated. Professionalism is a fluid concept informed by cultural and societal mores. Recently, physicians and trainees have drawn attention to the ways in which professionalism is weaponized against individuals who are perceived as being nonmajority or different. For example, women trainees and faculty perceive that more "necessary behavior" is required for them to gain recognition in the workplace. Trainees and physicians of color experience real harm in the form of microaggressions or disciplinary actions when, for example, their dress or appearance is seen as nonconforming to white norms. Professionalism requires rigorous efforts to earn the trust of all stakeholders, including colleagues and patients.

ETHICS AS FUNDAMENTAL TO MEDICAL PROFESSIONALISM

Service to society is the *raison d'être* of the professions. In medicine, physicians provide expertise to advance human health and to lessen the burden of suffering associated with illness. Medical professionals, including those in the field of psychiatry, have the opportunity to develop distinct expertise to help others. These professionals have the responsibility for creating and applying new knowledge, training others, and participating in leadership throughout the profession and broader society. These professionals also have the duty to ensure that colleagues uphold the clinical and ethical standards of their disciplines. Conscientious self-care is increasingly recognized as an ethical responsibility for health professionals, as is vigilance to avoid emotional and physical exhaustion and to address emerging health issues. The role of injustice and inequity in society in health disparities is a central concern of the field of psychiatry, especially in light of the potential vulnerability of people living with mental illness.

58.3 Correctional Psychiatry

ARYA SHAH, M.D., AND JHILAM BISWAS, M.D.

Correctional psychiatry functions at the boundaries of law and medicine and requires an understanding of ethics and the myriad ways that law impacts the practice of psychiatry. As a subset of forensic psychiatry, correctional work requires being aware of issues of ethics and morality and can be fraught with potential bias and conflicts of interest. Given a large portion of the psychiatric population interacts with correctional settings, psychiatrists benefit greatly from learning about how corrections and law enforcement engage with inmates.

Today, certain county jails in large cities are considered the largest psychiatric hospitals in the United States. Multiple factors, including legal, social, fiscal/health care reimbursement, and political, over the past 70 years have led to the current substantial presence of psychiatric and substance use disorders seen within American jails and prisons.

Some examples of these factors include reducing beds at state inpatient facilities, “zero tolerance” arrest, sentencing policies as part of the “war on drugs,” and the deinstitutionalization of many individuals with chronic and persistent mental illness without adequate community resources. The unintended consequence of these national policies is that it has criminalized mental illness.

Mental and substance-related disorders, as well as chronic medical conditions, are prevalent public health problems affecting individuals in U.S. correctional facilities, and these settings have become the default mental health system for high-risk populations. The sheer number of inmates with severe psychiatric disorders in the U.S. prison system and the “revolving door phenomena” in which many mentally ill people move continuously between homelessness and the criminal justice system represents a national public health crisis. This risk of reincarceration also exists among prisoners with co-occurring severe mental illness and substance use disorders.

In the postpandemic era, equitable health care among races is a key area of correctional psychiatry and must be addressed in the treatment, research, and advocacy of this patient population. Incarceration disproportionately affects Black Americans, and the data shows that living in a predominantly brown and black community heightens the risk a person will interact with law enforcement and corrections. Providing high-quality mental health care in corrections may be one way to address the inequities faced by disenfranchised minorities and a core area of criminal justice reform.

Over the course of the last decade, the imprisoned population has slowly come down from its height in 2010, but data shows the United States continues to hold a quarter of the world’s incarcerated population. The COVID-19 pandemic did cause a drop in incarceration rates from 2.1 to 1.8 million. While this has been a positive development, many argue the high reincarceration rate will again increase numbers if policies stay the same. Among the incarcerated population, around 20%, or an estimated 356,000, have a severe and persistent mental illness, that is, carry a diagnosis of a serious mental disorder such as schizophrenia, bipolar disorder, or severe depression.

Notably, not all correctional settings are the same, and there are many types. These include lockups, jails, state and federal prisons, U.S. Immigration and Customs Enforcement (ICE) detention centers, Bureau of Indian Affairs detention centers, U.S. military prisons, jails, and detention centers. There have been recent concerns regarding access to care and other medicolegal issues for persons with severe mental illness in the U.S. ICE system, which is discussed elsewhere in the literature.

The most common correctional settings for adults are jails and prisons. Jails are city- or county-operated correctional facilities that confine individuals involved in the criminal justice system who are awaiting trial or serving short sentences for misdemeanors. There are approximately 3,500 jails in the United States. Detention refers to the period following arrest in which an individual is held in secure custody prior to or after court proceedings. The amount of time a person is in jail varies (e.g., hours, days, weeks, typically 1 year or less). Some individuals may remain in jail for years for more serious charges while awaiting legal disposition of their case, or they may serve their sentence in a jail setting. There is significant variability in size, with some small rural jails holding 10 to 50 detainees and some major metropolitan jails holding 7,500 to 10,000 detainees.

A prison is a facility operated under the auspices of a state or federal government for the confinement of adults convicted of a felony whose sentences generally exceed 2 years. Individuals in prisons may be serving one or more life sentences, and some states have the death penalty. There are approximately 1,300 state and federal prisons in the United States.

Similar to adults, youth in juvenile justice settings face significant mental and co-occurring substance-related disorders, which represent a serious public health concern, and the need for services in the juvenile justice system is high. While involved with the juvenile justice system and family courts, youth may be housed within juvenile detention centers, reception or diagnostic centers, community-based or other residential treatment programs, or juvenile correctional facilities. Some juveniles may be held in county jails, and some youth may be transferred/sentenced to adult prison settings. In many states, certain felony offenses committed by adolescents are moved to adult criminal court. This practice has led to an increase in the detention and incarceration of younger offenders in adult jails and prisons. Data reflect rates of SMI among incarcerated adolescents that are substantially above those found in the community.

This chapter will present an overview of American correctional systems and provide background on the demographic and mental health landscape of the correctional population. The chapter will identify ongoing practical, legal, and ethical challenges that a psychiatrist may face while providing care in correctional settings. Finally, the chapter will also aim to make recommendations for psychiatric assessment and treatment in the correctional setting, discuss the roles of mental health clinicians in corrections, and identify phenomena that might influence the future of correctional psychiatric practice in the United States.

PSYCHIATRIC PATIENTS IN CORRECTIONAL FACILITIES

Mental Illness in the Correctional System

The importance of demographic studies of psychiatric disorders in correctional facilities cannot be overemphasized. For advocacy purposes and for public health considerations, the results of this research dramatically portray the critical need for psychiatric services in jails and prisons.

However, the true incidence and prevalence of psychiatric disorders in correctional facilities are difficult to obtain. Well-designed, carefully done epidemiologic studies are costly and complex to carry out, and because of the high inmate turnover rates, doing a point prevalence study of mental illness in jails is difficult. The best way to detect the incidence and prevalence of psychiatric problems in jails is to find cases on admission. Prison inmates stay for longer terms, and conducting a point-prevalence epidemiologic study of mental illness in this setting is more feasible. Despite these difficulties and limitations, the epidemiology of mental illness in correctional facilities is gradually becoming known. In a 2017 special report on mental health problems in prisoners and jail inmates, the Bureau of Justice Statistics estimated that 37% of prisoners and 44% of inmates had been diagnosed with a mental illness by a mental health professional. In general, most authorities now estimate that about 20% to 40% of the correctional population has serious and persistent mental illnesses. In 2010, the Treatment Advocacy center issued a report identifying that jails and prisons housed more than three times as many individuals with serious mental illness than did hospitals. Thus, in 2012, more than 350,000 seriously mentally ill offenders were incarcerated in the nation's jails and prisons. (This is contrasted to an estimated 35,000 patients in state psychiatric hospitals.)

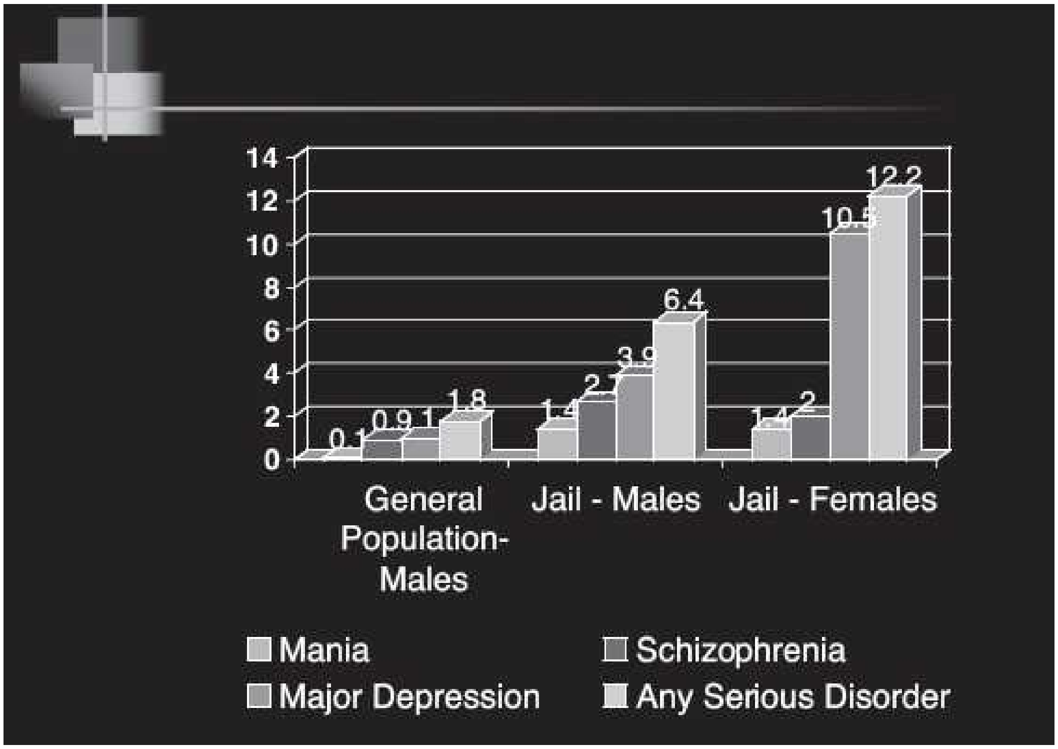

FIGURE 58.3–1. Serious mental disorders among the general population and among jail admissions.

Jails. With regard to jails, the few available epidemiologic jail studies highlight that after controlling for demographic differences between jail samples and the epidemiologic catchment area (ECA) samples, jail prevalence rates of mental illness are two to three times higher than those in the general population (Fig. 58.3–1).

Prisons. Because prison inmates stay for longer terms, there are more prison population-based epidemiologic studies of mental illness than there are in jails. The ECA study found that 6.7% of inmates in prisons had experienced schizophrenia at some point, compared to 1.4% of the U.S. household population. A number of studies reveal that, at any given time, a little more than 2% of the inmate prison population is in inpatient or residential psychiatric care.

More than 30% of male inmates and 78% of female inmates with mental illness reported prior physical or sexual abuse, and inmates with mental illness in correctional facilities are more likely than other offenders to have a higher prevalence of homelessness, unemployment, alcohol and drug abuse, and physical and sexual abuse before their current incarceration.

HISTORY OF CORRECTIONAL PSYCHIATRY IN THE UNITED STATES

Until recently, the judicial system maintained a “hands-off” policy with regard to conditions in jails and prisons, a doctrine that regarded the inner workings of correctional facilities as beyond the responsibility and authority of the courts and best left to correctional professionals.

It was during the 1970s, during the tidal wave of the civil rights movement, that various studies and court cases exposed the abominable conditions of health and mental health care in the jails and prisons of the United States. These findings led to significant reform of the correctional system and of correctional psychiatry and health care. The confluence of a number of interrelated forces spearheaded this reform, including professional organizational advocacy by the American Medical Association (AMA) and the American Psychiatric Association (APA), “conditions of confinement” lawsuits, which were now entertained by the courts, and the development of standards and guidelines for health and mental health care in jails and prisons.

Table 58.3–1.
American Psychiatric Association Position Statement on Psychiatric Services in Adult Correctional Institutions (2021)

The American Psychiatric Association Position on mental health services for individuals in adult incarcerated settings should minimally include:

1. Timely and effective access to mental health services screening, evaluation, and treatment, including an appropriate range of therapeutic interventions.
2. Necessary staffing levels to ensure access to care and to provide appropriate services.
3. Quality assurance and improvement reviews to identify and resolve inadequacies of care.
4. As therapeutic an environment as possible, optimized by support, guidance, and advocacy from mental health leadership and collaboration with correctional leadership. Mental health administration should be incorporated into the overall management of the facility.
5. Proper procedures, based on appropriate legal guidance, and staffing to safely administer involuntary medications when clinically indicated and when reasonable attempts at voluntary engagement in medication adherence have not been successful. This should not preclude psychiatric hospitalization if available and clinically indicated.
6. A balance and an effective partnership between security and treatment needs to ensure the effective delivery of mental health services.

Reprinted with permission from the Position Statement on Psychiatric Services in Adult Correctional Facilities (Approved by the Board of Trustees, December 2021). American Psychiatric Association. All Rights Reserved.

In 1974, the AMA carried out a survey of sheriffs administering local jails, which revealed that, in addition to frequently lacking mental health screening and testing resources, fewer than 20% of jails had facilities for caring for individuals with alcohol use disorder, only 10% had any facilities for inmates with drug addiction, and only 14% had facilities for inmates with mental illness. Studies of prison correctional health care revealed that prison correctional health care was no better than that in jails. The APA subsequently published a Position Statement on providing psychiatric care in correctional settings, which was prepared by the APA Committee on Psychiatry and the Law, with the most recent version published in 2018 (Table 58.3–1). In 1975, the Federal Law Enforcement Assistance Administration (LEAA) provided a grant to the AMA to upgrade correctional health care. The purpose of the grant was to develop a model correctional health care system and to distribute information on correctional health care issues. Another important goal was the development of a national accreditation program with correctional health care standards. In 1977, the AMA published its first jail correctional health standards; 16 jails were accredited for compliance that year. In 1979, the prison and juvenile correctional health care standards were published.

At the same time, the judicial system was establishing the unique legal context of psychiatric services in jails and prisons—that such services are constitutionally guaranteed. In 1976, the U.S. Supreme Court, in the case of *Estelle v. Gamble*, held it unconstitutional for prison officials to be deliberately indifferent to the serious medical needs of those in their custody, and in 1977, a federal court, in the case of *Bowring v. Godwin*, extended this requirement to psychiatric care.

In 1983, as an outgrowth of the LEAA-funded AMA program, the National Commission on Correctional Health Care (NCCHC) was established. The NCCHC consists of 37 professional organizations, including the AMA and the APA. It assists correctional institutions in upgrading their correctional health care services and, most importantly, has established correctional health care standards and correctional health care accreditation processes. These standards, which are revised regularly, represent the state of the art for correctional health care, and with their recently revised 2018 publication of the NCCHC's Standards for Mental Health Services in Correctional Facilities, the state of the art, as well as evidence-based practice, for mental health services in jails and prisons.

In 1989, the APA published Psychiatric Services in Jails and Prisons. This document, referred to as the APA Guidelines, was developed by correctional psychiatrists for correctional psychiatrists and described in detail the principles governing the delivery of psychiatric services in jails and prisons; the specific requirements for an adequate process of screening, evaluation, and treatment; the specific roles of the correctional psychiatrists; and the application of the principles and guidelines to specific populations. The second edition of the APA Guidelines was published in 2000; the third edition, now titled *Psychiatric Services in Correctional Facilities*, was published in 2016.

PERSISTING CHALLENGES IN CORRECTIONAL PSYCHIATRY

Despite the significant burden of psychiatric needs in correctional settings, there exist significant gaps and shortcomings in care within jails and prisons.

Shortage of Correctional Psychiatrists

The National Health Service Core (NHSC) maintains a database of correctional institutions that are designated Health Professional Shortage Area (HPSA) facilities that have a minimum of 250 inmates and a ratio of psychiatrists to inmates of at least 1:2,000. More than 450 correctional facilities nationally have been found to meet the criteria for Health Professional shortages in the database, with such figures likely representing an underestimate of the true count of correctional facilities with a shortage in psychiatric providers. Consequences of such gaps in care have been called to public attention; in the more recent landmark case of *Brown v Plata,* the Supreme Court recognized that as many as 72% of suicides in correctional settings likely related to inadequacies in mental health care, with wait time for receiving care as long as 12 months (Supreme Court Ruling 536, 2011).

The lack of adequate numbers of clinicians in correctional settings may be related to multiple factors. Currently, forensic exposure is sporadic in residency training. This lack of exposure to psychiatric practice in corrections can result in graduates feeling ill-equipped to practice in forensic settings. Furthermore, misconceptions related to justice-involved individuals receiving treatment, apprehension regarding provider safety, and belief that clinical care may be less fulfilling in correctional settings may all contribute to the lack of psychiatric clinicians choosing to build careers in the field. Exposure to forensic psychiatry in training has been proposed as a solution for countering ambivalence and increasing provider comfort with providing care in these settings.

Overcrowding

In 2006, more than 7.2 million people were on probation, in jail or prison, or on parole. At year-end 2006, this represented 3.2% of all U.S. adult residents or one in every 31 adults. State and federal prison authorities had jurisdiction over 1,570,861 inmates at year-end 2006: 1,377,815 in State jurisdiction and 193,046 in Federal jurisdiction. Local jails held 766,010 persons awaiting trial or serving a sentence at year-end 2006. An additional 60,222 persons under jail supervision were serving their sentence in the community.

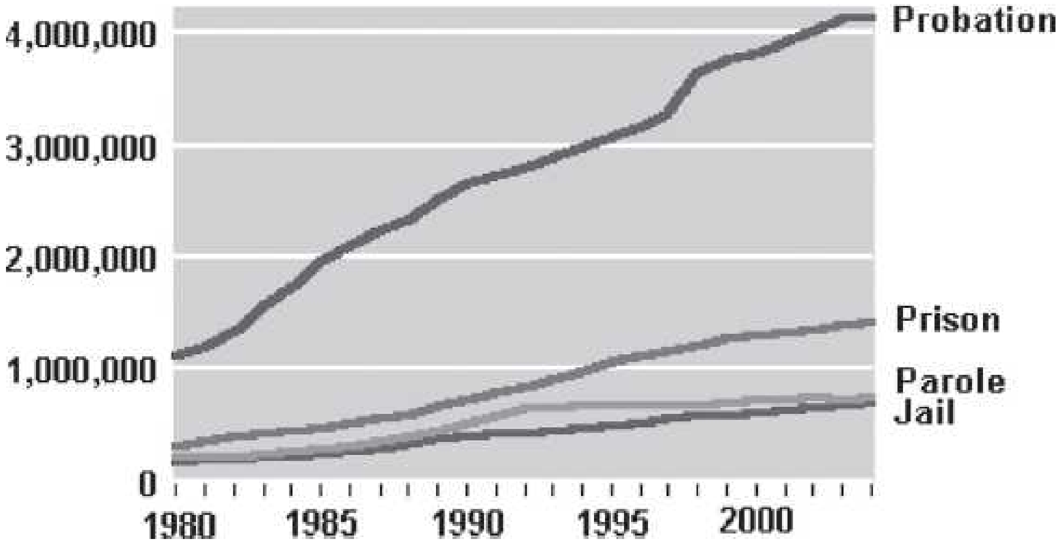

FIGURE 58.3–2. Adult correctional populations from 1980 to 2004.

The overcrowding that has resulted from the increase in the correctional population over the last three decades has made many large jails, such as the Cook County Jail in Chicago, the Los Angeles County Jail, and Harris County Jail in Houston, Texas, the country's largest mental institutions (Fig. 58.3–2).

Multiple historical factors have contributed to the current problem of overcrowding and over-representation of mental illness in our county's jails and prisons. With the discovery of chlorpromazine and its antipsychotic properties, there was growing optimism about the possibility of community-based care for individuals with serious mental illness who had previously been institutionalized. The phenomenon of deinstitutionalization in the 1960s involved the closure of state hospitals in hopes of transitioning psychiatric care into community-based mental health treatment programs. However, a variety of social, financial, and legislative factors ultimately contributed to inadequate funding of community mental health treatment centers, resulting in a system that was ill-equipped to manage the mental health needs of individuals requiring access to care. The combination of untreated mental illness and lack of access to care in the community have since contributed to the described “revolving door” of incarceration faced by many individuals with mental illness, contributing to the phenomena of “transinstitutionalization” and the over-representation of mental illness within our country’s justice system (Fig. 58.3–3).

The Criminalization of the Mentally Ill

Some of the factors contributing to the high rates of people with serious mental illness in the criminal justice system include, as reasons for the increased entry, the process of deinstitutionalization and its accompanying phenomenon of “transinstitutionalization,” the inadequate access to the seriously and persistently mentally ill to community treatment, the fact that these patients are arrested at disproportionately higher rates and often have co-occurring substance-related disorders, the prejudice that the mentally ill are more violent than other persons, and the use of jails and prisons as housing of last resort.

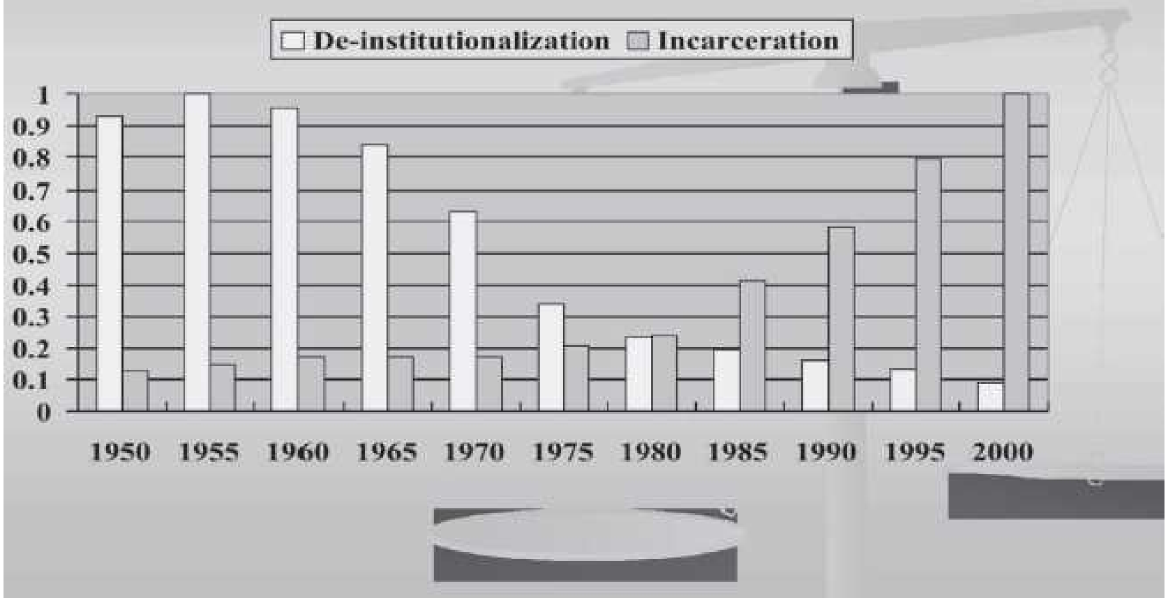

FIGURE 58.3–3. Transinstitutionalization from 1950 to 2000.

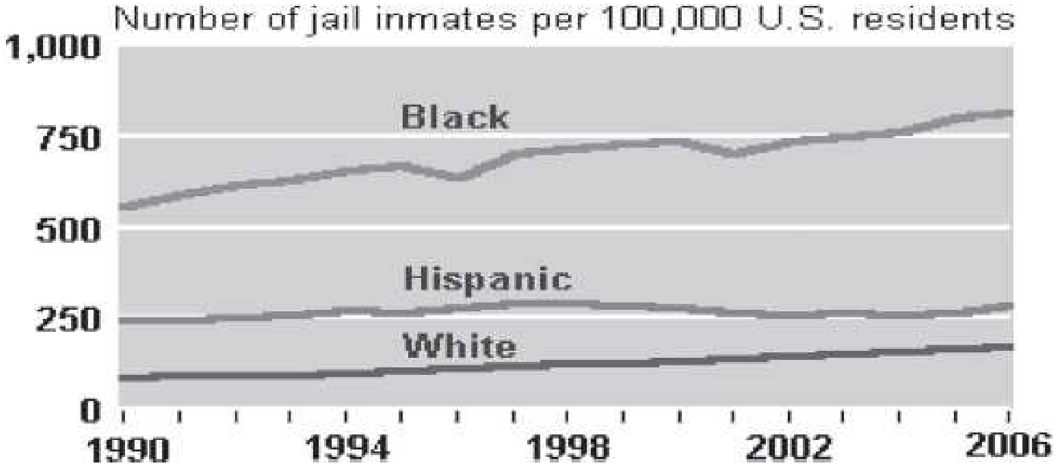

FIGURE 58.3–4. Jail incarceration rates by race and ethnicity, 1990 to 2006.

There are additional problems with discharge planning and reentry into the community, including the fact that these patients spend long periods of time incarcerated, the pathogenic nature of incarcerated environments, the lower rates of parole, and the higher rates of recidivism due to inadequate community mental health services.

The United States has the largest percentage of its population incarcerated than any other country in the world. Since 1989, the National Drug Control Strategy, which called for a mandatory minimum sentence for drug crimes, caused the jail and prison populations to grow at a rapid rate. In 1985, the percentage of sentenced drug offenders was approximately 13%. Currently, it is more than 30%. The importance of the relationship between the increase in the number of inmates incarcerated for drug offenses and the disproportionate increases in the numbers of female, nonwhite, and foreign-born inmates cannot be overstated.

Racial Inequity

In addition to the well-recognized phenomenon of mental illness being over-represented in the correctional system, racial disparities among individuals housed in jails and prisons have been viewed as evidence of significant care inequity (Fig. 58.3–4).

While the presence of mental illness alone is a risk factor for justice involvement and incarceration, disparities in access to community treatment may contribute to additional racial inequities. A report from the Office of the Surgeon General identified that racial and ethnic minorities not only have less access to community mental health treatment than do white individuals but that even when received, the care is of poor quality. It is possible that such disparities in the community influence the disproportionate number of people of color in the correctional system. Despite making up 13% of the general population, African Americans make up 40% of individuals who are currently incarcerated. Furthermore, there is evidence that individuals of color may be less likely to receive mental health treatment within jails and prisons, with mental health symptoms more likely to be viewed as criminal and to be met with punitive action. Such phenomena highlight the importance of the continued study of structural barriers to equitable access to treatment and enhanced recognition and treatment of mental illness in populations who have historically had inequitable access to care.

THE LEGAL AND ETHICAL PRINCIPLES UNDERLYING THE PRACTICE OF CORRECTIONAL PSYCHIATRY

Landmark Cases in Correctional Psychiatry

In the 1970s, the crucial years of the reform of the correctional system, a series of court decisions established the principle that psychiatric services in the jails and prisons of the United States are constitutionally guaranteed. This legal doctrine holds that under the Eighth Amendment of the U.S. Constitution, which prohibits “cruel and unusual punishment,” whenever a state or the federal governmental entity takes custody of a person, it must provide for the necessities of life that the person otherwise is unable to obtain. These include food, clothing, shelter, and medical care, which include psychiatric care.

In 1976, the Supreme Court, in the case of *Estelle v. Gamble*, held it unconstitutional for prison officials to be deliberately indifferent to the serious medical needs of those in their custody, and in 1977, the federal court case of *Bowring v. Godwin* extended this requirement to psychiatric care. In 1980, another federal court case, *Ruiz v. Estelle*, listed a number of specific components of mental health care components that are required in correctional facilities, including but not limited to the involvement of trained mental health professionals, utilization of systematic screening and evaluation, adequate monitoring of methods and amounts of medications administered, maintenance of a confidential medical record, and implementation of a suicide prevention program.

In 1989, the case of *Langley v. Coughlin* listed a number of other specific criteria that, if not met, could provide a basis for successful inmate legal claims. Many of these criteria explicitly required providing for so-called secondary or supportive rights, such as taking psychiatric histories and maintaining medical records, in recognition of the fact that such rights are required to facilitate the primary right to diagnosis and actual care. *Langley v. Coughlin* also explicitly requires that care not be limited to psychotropic medication.

Madrid v. Gomez, in 1995, a State of California Department of Corrections legal case, added several factors that may determine the constitutionality of a correctional mental health system. These included that inmates should be able to communicate needs to medical staff, have access to individualized treatment, and reserve the right to a hearing and procedural protections prior to involuntary treatment; furthermore, institutions were required to implement symptoms of quality assurance and hire staff that are competent and trained in the needs of those with mental illness within the correctional system.

In addition to these constitutional mandates, jail and prison mental health services may be required to meet other legal requirements, such as those associated with federal laws (such as the Americans with Disabilities Act), state laws, and other regulations related to liability for medical malpractice.

Mental health in correctional facilities is considered a constitutional guarantee. A lack of it is considered a violation of the Eighth Amendment of cruel and unusual punishment as determined by *Estelle v. Gamble*. However, substance use is variably included as part of mental health and often depends on local courts and governments. The position of the courts has been that the provision of care and treatment in cases of substance use disorder (e.g., for drug abuse) in jails and prisons is not considered an aspect of psychiatric care and, therefore, is not considered constitutionally required. However, there is such an obvious need for the treatment of substance use disorders in jails and prisons that it is usually included in correctional programs.

Ethical Considerations of Correctional Psychiatry

Correctional mental health providers should follow the standards of professional ethics as set out in the APA's Annotations Especially Applicable to Psychiatry to the AMA's Principles of Medical Ethics.

Although the Preamble to the AMA's Principles states, "A physician must recognize responsibility to patients first and foremost," it then adds the words "as well as to society." Correctional psychiatric practice presents unique challenges related to how the psychiatrist's duties to the patient may clash with their duties to the department of correction, which can be regarded as an aspect of the correctional psychiatrist's duties to "society."

Ethical conflicts may manifest in various features of mental health care in correctional settings. In the correctional setting, there is a conflict between the two distinct roles of the correctional psychiatrist: As the inmate's treating physician and as an employee and agent of a local, state, or private correctional agency. This problem is known as that of "dual loyalty" (also called the "the double-agent problem"). Therefore, while the concepts of autonomy and nonmaleficence are central tenants to the practice of medicine, both of these values may be at odds with correctional perspectives and policies, and the correctional environment might threaten to coerce professional judgment and actions into meeting security needs rather than the mental health needs of individual inmates. Such conflicts can affect the doctor–patient relationship, and the unique power dynamics existing within the correctional setting necessitate that mental health providers consistently monitor unintended identification with correctional authorities and countertransference with inmates. The APA has set forth in its guidelines that the inherently coercive settings of jails and prisons might create additional difficulties for the correctional psychiatrist in regard to obtaining informed consent. It is interesting to note that one legal case stated that it is impossible to obtain true informed consent in this setting.

Confidentiality also presents unique considerations in the correctional setting. Although the usual principles of psychiatric confidentiality apply to the delivery of psychiatric services in jails and prisons, there are special needs presented by these settings, especially in relation to security and safety. The APA Guidelines state, "The rights of the patient to . . . confidentiality must be weighed against the needs of other inmates as well as the institutional needs of safety and security." Furthermore, the limitations of privacy in correctional settings have been acknowledged, given the unique organizational structure within the facility. While the NCCHC Standard on "Privacy of Care" in corrections requires that "mental health services are conducted in private and carried out in a manner designed to encourage the patient's subsequent use of services . . . in private, without being observed or overheard by staff or inmates," the standard goes on to acknowledge the limits of privacy with imminent risk is of concern, as well as acknowledging that "in corrections mental health triage commonly occurs at cell-side. As the triage discussion becomes more involved than a simple triage, the clinician should be aware of the need to maintain privacy and move the patient to a clinical setting."

It is critical for psychiatrists and other mental health staff working in correctional settings to define and maintain their role as a clinician, working in the best interests of the patient, as opposed to a forensic evaluator, or as an agent of the court, law enforcement, or of the state or local jurisdiction. Without a release of information, treating psychiatrists should avoid verbal or written communication with attorneys and other court personnel, and they should avoid inappropriate communication with the media. It is also recommended that correctional psychiatrists specify clearly any limits on the usual precepts of confidentiality before initiating treatment, except in emergencies. However, this notice may be presented to the inmate in general terms, such as applying to situations in which the patient or the institution may be at risk.

On the contrary, the correctional psychiatrist must be able to share relevant confidential information with facility administrators (on a "need-to-know" basis) when it relates to the medical management of a patient, security issues, or a patient's ability to participate in programs. Similarly, it is appropriate that there be communication with nonclinical staff regarding an inmate's significant mental health needs that must be considered in classification decisions to preserve the health and safety of that inmate, other inmates, or staff.

The correctional psychiatrist should be sensitive to the fact that confidentiality is especially important to those for whom the lack of confidentiality might have serious legal and other consequences, such as those detainees with pending legal charges. Some practical suggestions for psychiatrists and other mental health staff might include the avoidance of exploration into the details or circumstances of the alleged criminal act(s) and the individual's state of mind, criminal intent, mitigating factors, or other defense strategies. Similarly, at risk are those who have experienced sexual violence, sex offenders, or persons with HIV/acquired immunodeficiency syndrome (AIDS).

Collecting Forensic Psychiatry Information in a Jail or Prison

The collection and use of forensic information by the correctional psychiatrist present a unique clinical and ethical challenge for mental health clinicians in this setting. The APA Guidelines set out the "distinction [that] must be drawn between information obtained by a correctional psychiatrist in the course of treatment, and information obtained from the inmate in the course of an evaluation for non-treatment purposes."

When correctional authorities ask correctional psychiatrists to collect information for forensic purposes, the NCCHC standards support the refusal of the correctional psychiatrist to do evaluations of inmates for use in adversarial proceedings or to order blood tests to determine drug or alcohol use (unless it is for clinical reasons). These matters are of such concern to the NCCHC that it has promulgated an explicit standard prohibiting health care workers from collecting "forensic information." The standard on Forensic Information in the Standards for Mental Health Services in Correctional Facilities states, "Mental health staff are prohibited from participating in the collection of forensic information," which is defined as "physical or psychological data collected from an inmate that may be used against him or her in disciplinary or legal proceedings." The intent of the standard is to ensure the preservation of the treatment relationship between the provider and the patient.

The NCCHC standard goes on to state that "where state laws and regulations require that such acts be performed by health/mental health staff, the services of outside providers or someone on the institution's staff who is not in a therapeutic relationship with the inmate is obtained." Relevant also are the Ethics Guidelines for the Practice of Forensic Psychiatry of the American Academy of Psychiatry and the Law (AAPL), which deal with this issue explicitly, noting, "When a patient is involved in parole, probation, conditional release, or in other custodial or mandatory settings, psychiatrists should be clear about limitations on confidentiality in the treatment relationship and ensure that these limitations are communicated to the patient."

PSYCHIATRIC TREATMENT IN JAILS AND PRISONS

The Policy Goal of Psychiatric Treatment in Jails and Prisons

According to the APA Psychiatric Services in Correctional Facilities (Third Edition):

The fundamental policy goal for correctional mental health care is to provide the same quality of mental health services to each patient in the criminal justice system that should be available in the community. This policy goal is deliberately higher than the "community standard" that is called for in various legal contexts, because resource restrictions on community care can sometimes limit the adequacy of available services. Correctional systems provide additional challenges not present in the community, given that incarcerated persons have no options for care other than what is provided in the correctional facility.

The Purposes of Psychiatric Treatment in Jails and Prisons

Psychiatric disorders and psychiatric comorbidities are overrepresented in correctional populations compared with the general population. Correctional facilities and systems are, therefore, legally obligated to address the medical and mental health care needs of individuals in their placement. The purposes of psychiatric treatment in jails and prisons as set out by the APA Guidelines are listed in Table 58.3–2. These principles are echoed in the NCCHC Standards, which add that the goal is the "best level of functioning" and "In the correctional setting, as in most other environments, the immediate objective of mental health treatment is to alleviate symptoms of serious mental disorders and prevent relapses to sustain patients' ability to function safely in their environment."

Models of Health Care in Jails and Prisons

Different correctional settings have different organizational models for health care delivery, and it is important that correctional psychiatrists become familiar with the model that their institutions follow. In many facilities, medical services and mental health services may be under the same or under separate authorities with different administrators and lines of reporting and supervision. Variations include situations in which the correctional psychiatrist is a full-time or part-time state, federal, or county employee, employed by a university or private health care system, or is a locums tenens, part-time or temporary individual contractor providing mental health services to any of the above or alternatively an employee or individual contractor for a national for-profit organization that is responsible for medical and/or mental health care services.

Table 58.3–2.
The American Psychiatric Association Guidelines on Purposes of Psychiatric Treatment in Jails and Prisons

To relieve the unnecessary extremes of human suffering
To make the correctional facility safer for everyone who lives, works, or visits there
To enable patients to avail themselves of the rights of due process
To permit inmates the opportunity to make use of programs offered
Correctional settings is public psychiatry as jails are the new psychiatric hospitals

Jails and prisons differ in the scope of mental health services that are provided. Jails process most detainees who have a short length of stay, and, accordingly, jails are primarily concerned with the stabilization and management of acute conditions such as acute psychosis, substance intoxication, withdrawal, and suicide prevention. While a person is in jail, the purpose of mental health treatment is to prioritize the detainee's health and safety, but, when appropriate, this might also include the goal and outcome of restored competency to be arraigned or restored competency to stand trial so that their pending legal proceedings may resume. Because this is a forensic and nonclinical role, typically, jail psychiatry staff are not involved in the assessment of whether an individual is competent or is not competent to stand trial. Similarly, they are typically not involved in the treatment of restoration of competency to stand trial, but this may vary by location (and whether the jail has a competency restoration program on-site or if this is a separate on or off-site program). Of course, once an individual returns to jail, ensuring continuity of care and the psychotropic medications (typically initiated in the state hospital or competency restoration program) and other treatments is essential and can be very challenging.

In a prison setting, the outcome might be to return the inmate to the general population with the ability to participate in prison programs, including clinically indicated mental health programs, psychotropic medication administration, monitoring, further psychiatric evaluation and treatment, and preparation for release. Prisons should be considered communities in which individuals spend many years of their lives. As such, prisons need a greater range of services that emphasize long-term support for particularly vulnerable individuals, including sheltered and/or residential units (for individuals with stable conditions who cannot be placed into the general population), case management, individual and/or group therapies, and other in-cell programming materials (self-study materials and the like). Programs should be available to prison inmates who repeatedly self-injure, mutilate, those with the need for frequent/repeated psychiatric hospitalizations who might require step-down programming, followed by sheltered or residential unit placement with other similar offender patients, and more intensive treatment to ensure medication compliance, monitoring of their activities of daily living (ADLs), and medication and illness teaching and education, than that which is typically available within general population settings. Sheltered housing and tailored assessment and treatment programs for individuals with developmental disabilities are also necessary.

Issues in Administration and Management

WRITTEN POLICIES AND PROCEDURES. Mental health administrative personnel in a jail or prison should establish written policies on such critical issues as (1) staffing patterns, (2) admission, (3) referral, (4) discharge criteria, (5) health care information management, and (6) interagency and intra-agency communications, especially with regard to confidential medical and mental health information.

THE FACILITY INFORMATION TECHNOLOGY SYSTEM: NEEDS ASSESSMENT AND ALLOCATION OF RESOURCES. With regard to a correctional facility's information technology system, the APA Guidelines point to a capacity for "needs assessment" and state: "It is critical that the administration of the correctional facility have the capacity to gather and assess information relevant to the prevalence of mental illness in the facility because this data forms the basis of the needs assessment that assures an adequate level of care."

THE FACILITY QUALITY ASSURANCE PLAN. One important aspect of the reform of the correctional mental health system calls for each jail or prison to have a quality assurance plan that systematically reviews the quality of mental health services and the efficiency and effectiveness of the utilization of staff and resources in the delivery of services.

ACCREDITATION AND STANDARDS. The NCCHC has become the major organization establishing correctional health care standards and providing correctional health care accreditation. In 2007, the NCCHC published separate standards for the accrediting of mental health programs in jails and prisons, Standards for Mental Health Services in Correctional Facilities. The most current NCCHC standards include the Jail (2018), Prison (2018), Mental Health (2018), and the Juvenile Standards (2018). The NCCHC also has developed standards for opioid treatment programs within correctional settings, which are linked to specific federal regulations.

Jails, prisons, juvenile detention, and other correctional facilities may be accredited by the NCCHC (an offshoot of the AMA as described previously), the ACA, The Joint Commission, or a combination of the above. Although national accreditation is typically voluntary, it is often a contractual requirement for universities, other health care systems, and private vendors who provide health care services to correctional systems. In addition, when facilities undergo investigation or litigation or are placed in receivership or federal oversight, they are often mandated to establish and maintain national accreditations.

Access to Mental Health Care and Treatment in Correctional Settings

Constitutional provision and statutory law require that an inmate in a correctional setting have access to mental health treatment, and this principle is emphasized in the APA Guidelines on Psychiatric Services in Jails and Prisons, which state, “Timely and effective access to mental health treatment is the hallmark of adequate mental health care.” In addition, it is striking to note that the very first standard of the NCCHC’s Standards for Mental Health Services in Jails and Prison is on access and requires that “inmates have access to care to meet their serious mental health needs,” defining access to care as meaning that “in a timely manner, a patient can be seen by a clinician, receive a professional clinical judgment, and receive care that is ordered” and adds that this principle is “the foundation upon which National Commission on Correctional Health Care standards are based.”

Furthermore, this section notes that access to care procedures should be flexible enough to accommodate inmates with mental illness and functional deficits and that such deficits can manifest as the following:

- Inability to recognize emerging health or mental health need
- Inability to follow usual procedures in requesting health or mental health care
- Severe anxiety or suspicion preventing follow-up care
- Behavior that makes care especially challenging

Barriers to Inmates Receiving Services. To determine whether there is adequate and appropriate access to psychiatric treatment, it is critical that the treatment delivery system be analyzed to ensure that there are no unreasonable barriers to patients' receiving services. Some examples of unreasonable barriers listed in the APA Guidelines are listed in Table 58.3–3.

Table 58.3–3.
American Psychiatric Association Guidelines on Examples of Unreasonable Barriers to Patients' Receiving Psychiatric Services

Instituting or allowing disincentives that would deter a patient from seeking care for their legitimate mental health needs
Interfering with the prompt transmittal of a patient's oral or written request for care
Allowing unreasonable delays before patients are seen by mental health staff or outside consultants
Charging fees or costs that prevent or deter patients from seeking care
Punishing an inmate for seeking or refusing care

Staffing. The effectiveness of any correctional psychiatric system is largely dependent on staffing considerations. Staffing must be sufficient to ensure that every inmate with serious mental illness or in psychiatric crisis has timely access to evaluation by a competent mental health professional. More important than the number of staff is access to adequate care. Accordingly, none of the national correctional health care standards mandates staffing patterns other than that there be an adequate number and type to meet the needs of the population.

Screening. In jails and prisons, screening is critical, and, not surprisingly, both the APA Guidelines and the NCCHC Standards emphasize the importance of appropriate screening. The APA Guidelines describe in detail the sequence of screenings and assessments that lead up to treatment (Table 58.3–4).

For example, the APA Guidelines describe the progression in regard to an individual with a substance abuse disorder who might present while receiving mental health screening with any of a variety of medical, neurologic, or psychiatric problems. The receiving mental health screening instrument should include questions relating to the individual's use of alcohol and other drugs, the patterns of use, and observations related to whether the offender is under the influence of alcohol or drugs or experiencing withdrawal symptoms. The Guidelines note that the correctional psychiatrist should have an important role in the development of the screening instruments, in the training of staff in its use, and in educating correctional security, medical, and mental health staff about the signs and symptoms of intoxication and withdrawal.

A positive mental health screening for substance intoxication should trigger an immediate mental health screen for the presence of depressed mood and/or suicidal ideas. Similarly, the intake mental health screening should include questions on an inmate's history of alcohol and other drug use, as well as observations for the presence of signs of intoxication or withdrawal symptoms. The brief mental health assessment and the comprehensive mental health evaluation are particularly important in ensuring a proper diagnosis as the basis for the appropriate clinical management of an inmate with a substance use problem.

Table 58.3–4.
American Psychiatric Association Guidelines on Sequence of Screening and Assessments Leading up to Treatment

- Screening
  - Receiving mental health screening
  - Intake mental health screening
- Evaluation
  - Brief mental health assessment
  - Comprehensive mental health evaluation
- Intervention

The NCCHC notes that "receiving screening" is the means by which "newly admitted inmates' emergent or urgent mental health needs are identified and met through an immediate referral to mental health staff."

Both the APA and the NCCHC require a subsequent “intake” screening that must take place within 14 days. The step-by-step sequence ensures that an inmate who is identified through reception screening, intake screening, or by various processes at any time thereafter (including self-referral) as possibly in need of mental health treatment is provided with a suitable mental health evaluation.

Sick Call and Nonemergency Mental Health Care Requests and Services. Although the correctional psychiatrist works with inmates by appointment in an office situation if possible, in most correctional facilities, access to general health care is by means of “sick call.” The NCCHC Standards are quite specific and require that “all inmates have the opportunity daily to request mental health care” and that “verbal or written requests for mental health care are received daily by mental health staff and triaged within 24 hours.” There is a separate NCCHC standard for emergency services, and emergency mental health care is defined as “care for an acute mental illness that cannot be deferred until the next scheduled mental health clinic or routine appointment,” which must be available 24 hours a day, 7 days a week.

Referral. Emphasizing that within a correctional facility, the referral process is critical, and noting that this can be simple or complex, depending on the facility, the urgency of the situation, and the mental health coverage provided, the APA Guidelines state that the referral process, as set out in the facility’s operating standards, should be time constrained and specifically define the roles of the various participants, that the maximum time for response to each referral should be stated, and that timely referral and response should be designated as indicators of quality care.

Consultation. An important role of the correctional psychiatrist is to take the initiative in providing consultation to staff with regard to certain situations. Some of these are listed in the NCCHC Standards, such as consulting with regard to inmates who have a chronic illness (i.e., asthma, heart disease, diabetes, and hypertension) or communicable disease (e.g., HIV, hepatitis, syphilis, gonorrhea, or chlamydia); counseling patients coping with the psychological effects of their disease and consulting with regard to inmates who are physically or developmentally disabled and either assisting staff in managing such inmates or providing behavioral consultation so that the inmate can deal with the emotional and attitudinal consequences of their disability during incarceration. Consultations might also be called for with regard to inmates who are chemically dependent; pregnant or have recently given birth, for example, to minimize the postpartum phase and separation anxiety from the newborn; and of course, older adults or terminally ill inmates.

The Therapeutic Milieu for Mental Health Treatment. Table 58.3–5 lists the APA Guidelines conditions that would contribute to a therapeutic milieu for treatment.

Evidence-Based Treatment and Prescribing

Correctional psychiatrists must strive to provide evidence-based treatment as the standard of care in jails and prisons. Evidence-based treatments can be defined as treatments that, in appropriate studies, (1) have been rigorously tested, (2) have yielded consistent, replicable results, and (3) have proven safe, beneficial, and effective for most people diagnosed with the particular mental illness. While some researchers might argue over the standards by which an intervention or treatment approach is judged to be evidence-based, there is general agreement that the term and designation imply that a given practice has withstood rigorous scientific examination

Table 58.3–5.
American Psychiatric Association Guidelines on Conditions That Contribute to a Therapeutic Milieu for Treatment

A therapeutic milieu implies the following conditions:

- A sanitary and humane environment
- Written procedures and adequate staffing to permit adequate observation
- Adequate allocation of resources for the prevention of suicide and assault
- Medical and mental health staff available to provide adequate treatment and supervision
- Social interactions that foster recovery
- The ability to transfer an inmate to an appropriate mental health facility when the foregoing conditions cannot be met

The public mental health system must take steps to ensure that practice keeps pace with research. Because correctional psychiatry is a critical part of public psychiatry, it is appropriate to quote from the Report of the Criminal Justice/Mental Health Consensus Project, which describes the development of the concept as it promotes the utilization of evidence-based practices in public psychiatry:

> *In recent years, enormous advances have been made in treatments available for persons with mental illness. New medications have emerged; new services, supports, and interventions have proven effective. Researchers have conducted studies and collected data—they have developed an "evidence-base"—which demonstrate the effectiveness and applicability of some of these treatments and approaches.*

Of note, The APA publishes Practice Guidelines that provide evidence-based recommendations for the assessment and treatment of a wide range of psychiatric disorders of considerable importance to correctional psychiatrists, including acute stress disorder and post-traumatic stress disorder (PTSD), bipolar disorder, borderline personality disorder, psychiatric disorders related to HIV/AIDS, major depressive disorder, obsessive-compulsive disorder (OCD), panic disorder, schizophrenia, substance use disorders, suicidal behaviors, and others.

It is generally recommended that psychiatrists should use psychotropic medications in a safe and clinically appropriate manner and after a review of the potential risks, benefits, side effects, and alternatives. As with any mental disorder, barring maintenance treatment, it is unwarranted to prescribe psychotropic medications in the absence of distinct target symptoms or when placement and mental health follow-up services are unclear. To avoid risk management problems, it is generally recommended that medication be used according to U.S. Food and Drug Administration (FDA)—approved indications and doses, and if this is not preferred, then it is suggested that the correctional psychiatrist obtain and document a second opinion.

Precautions against abuse are necessary, and so, for example, it is recommended that directly observed therapy (DOT), crush and float, or other strategies be implemented for medications with particular overdose or bartering risks. The risk of medication diversion is an additional consideration, including diversion of medications with CNS effects that are maximized by nasal insufflation, injection, and other means of administration.

Involuntary Treatment in Correctional Psychiatry. Because involuntary treatment is complex and changes depending on the jurisdiction, the APA Guidelines say only "the actual institutional policies and the decisions of the correctional psychiatrist in regard to the right to refuse treatment should conform with the rules and procedures of the jurisdiction in which the facility is located."

On the contrary, the importance of this subject is highlighted by the fact that there are two separate NCCHC standards that apply. The first, Informed Consent and Refusal of Mental Health Care, states, "All examinations, treatments, and procedures are governed by informed consent practices applicable in the jurisdiction" and notes that "the intent of this standard is to support the ethical principle that patients have the right to accept or refuse mental health interventions."

The second NCCHC standard, Emergency Psychotropic Medication, states, "Mental health staff follow policies developed for the emergency use of forced psychotropic medications as governed by the laws applicable in the jurisdiction" (the definition of "forced medications" is "those given without the patient's consent").

It should be noted that the terminology used in the NCCHC Standards is dramatically different from that generally used in psychiatry. As a rule, psychiatric facilities use terms such as "treatment over objection" or "refusal of medication." The Standards focus on the word "forced" and its implications. Thus, the discussion of the latter standard states:

> *This standard's intent is to have a clinically approved protocol for emergency situations when an inmate is dangerous to self or others due to a medical or mental illness and when forced psychotropic medication may be used to prevent harm, based on a prescriber's order. The standard supports the principle that psychotropic medication may not be used simply to control behavior or as a disciplinary measure.*

Treatment Planning. The correctional psychiatrist has been trained as early as medical school to understand the importance of a detailed, in-depth, professional treatment plan. In any context or location, this requirement is a crucial reflection of the necessary standard of medical and psychiatric care. This is reflected in the APA Guidelines, which, with regard to discharge planning, notes that "it is recommended that discharge planning be a part of the initial treatment plan." Similarly, the NCCHC Standards require that "mental health services are provided according to individual treatment plans." The standards examine this subject in considerable detail, requiring that "patients receive care that is tailored to their individual needs . . . [including] consideration of cultural and language differences."

Peer-to-Peer Programs. Peer-to-peer programs have proven their worth in prison ministries, chaplain volunteers, and other spiritual ministries. Other peer activities may include volunteer work, providing care and training to service dogs for Veterans, and other individuals with disabilities, for example, the Patriot Paws programs. There are other self-help peer-to-peer organizations such as Alcoholics Anonymous (AA) and Narcotics Anonymous (NA). This concept is being extended into areas of reentry and continuing postincarceration support.

The APA Guidelines state, "As safety and security allow, self-help and peer support programs or activities contribute to the overall goals of the psychiatric services and where and when available should be promoted and encouraged."

However, within the correctional community, this is not an uncontroversial area. Concerns about the power of inmate workers were cited earlier. There are valid security concerns about prior inmates working within a correctional facility.

Suicide Prevention. The risk of suicide is dramatically higher among incarcerated jail and prison inmates than among the population at large. Suicide rates for men in jails are approximately 9 to 15 times higher than for the general population, and prison suicide rates are approximately 1.5 times higher than in the general population. An increased risk of suicide associated with mental illness also has been found. Researchers examined psychiatric disorders and completed suicide in the nation's largest state prison system, and their findings highlight the importance of maintaining suicide prevention programs in correctional settings with particular emphasis on screening and monitoring of patients with severe psychiatric disorders. It is further a legal requirement that every jail and prison must have a suicide prevention program that identifies and responds to each suicidal inmate and takes an active approach to their management.

An essential standard from the Jail, Prisons, Juvenile and Mental Health Standards of the National Commission outlines that an "adequate" suicide prevention program in a particular jail or prison should include the following components:

- Training for all staff who interact directly with inmates to recognize warning signs and intervene appropriately with individuals at risk for suicide.
- A formal and detailed suicide risk assessment process.
- Identification of inmates at increased risk of suicide through screening at or near the time of admission to the facility and through referral at any time during an individual's incarceration.
- An effective and well-understood referral system that allows staff and inmates to bring a suicidal inmate to the prompt attention of a mental health clinician.
- Timely evaluation by a mental health clinician to determine the level of risk posed by a referred inmate.
- Timely implementation of monitoring interventions such as close observation (at least every 15 minutes), continuous monitoring, alternative housing, or referral to a higher level of care (e.g., infirmary or hospital). When indicated, a psychiatrist either on call or in person assists in the decision about interventions. Any mental health clinician may order an increase in monitoring level, but a decrease in level may be ordered only by a psychiatrist or doctoral-level mental health clinician after an in-person evaluation.
- Housing options that allow for adequate monitoring of suicidal inmates by staff. Suicidal inmates should not be placed in isolation settings without continuous monitoring. Continuous monitoring for active suicidality should occur regardless of housing location. Supervision aids such as video monitoring may be used as a supplement to, but not as a replacement for, active staff monitoring.
- Communication among mental health, correctional, medical, and other staff of the specific needs and risks presented by a suicidal inmate.
- Timely provision of mental health services, including medication, individual and group therapies, and crisis intervention, for chronically or acutely suicidal inmates.
- Accurate, behaviorally specific, and highlighted documentation in the medical record of behaviors or statements that indicate suicide risk.
- Quality improvement reviews with psychiatric staff participation in suicide attempts and completed suicides to help prevent future occurrences.
- Critical incident support, opportunities for peer-to-peer discussion, and availability of Employee Assistance Program support for completed

suicides to assist staff and inmates in dealing with feelings of guilt, fear, grief, and anger.

HIGH-RISK PERIODS. It is obvious that an inmate might become suicidal at any point during incarceration. The high-risk periods that both the APA Guidelines and the NCCHC Standards emphasize are listed in Table 58.3–6.

Table 58.3–6.
Periods of High Risk for Suicide in a Jail or Prison

At the time of admission to a lockup, jail, or prison
After new legal problems (e.g., new charges, additional sentences, institutional proceedings, denial of parole)
After receiving bad news regarding one's self or one's family (e.g., a serious illness in the family or the loss of a loved one)
After suffering humiliation or rejection (e.g., sexual assault)
On being placed in administrative segregation or other specialized single-cell housing assignment
In the early stages of recovery from severe depression

Monitoring for and Preventing Self-Harm. Although there are many more suicide attempts and incidents of nonlethal self-harm than completed suicides, any threats of self-harm or self-injurious behavior must be taken seriously. Self-harm behaviors, regardless of motivation, can result in significant morbidity and mortality. For this reason, even behaviors that do not lead to injury should be taken seriously and not dismissed as merely "suicidal gestures."

Because self-harm is hard to control, it is a serious challenge for correctional officials and a complex clinical situation for the correctional psychiatrist, who must determine whether the self-harm is the result of a mental disorder. This requires a variety of means to assess the problem, including risk assessment methods and protocols and might require temporary housing in a mental health unit.

When self-mutilation is determined not to be the product of a mental disorder, the inmate may be denied admission to a mental health unit. This may confuse family members, attorneys, courts, patient advocates, and correctional authorities, who view such behavior as a sign of mental instability. It is, therefore, essential that the correctional psychiatrist follows clear protocols for self-harm to determine whether it is a psychiatric symptom, a manipulative gesture to escape a dangerous situation, or an effort to manipulate the system for personal gain. Careful and thorough documentation and communication with custody personnel are the key factors. Treatment, however, must be individually tailored and calls for a team approach.

Seclusion and Restrain in Correctional Psychiatry. Both the APA and the National Commission have addressed the complex issue of seclusion and restraint in correctional facilities. In 2006, the APA published the Resource Document on the Use of Restraint and Seclusion in Correctional Mental Health Care, which provides a detailed and nuanced discussion of this complex topic. It is strongly recommended that every practicing correctional psychiatrist carefully study and review this document. It "discusses the use of seclusion or restraint for purposes of mental health intervention in jails and prisons, in contrast to its use for correctional purposes (i.e., specifically custody reasons)."

With regard to the correctional setting specifically, this APA Resource Document details such matters as the location where the restraints or seclusion are being employed, the time frames that are required, and the devices that are permissible under various circumstances. The same principles are contained in the NCCHC Standard entitled Use of Restraint and/or Seclusion for Mental Health Reasons, which states, "Clinically ordered restraint or clinically ordered seclusion are available for patients exhibiting behavior dangerous to self or others as a result of mental illness." The standard further distinguishes between "custody" restraint or punitive segregation initiated for security concerns and "clinically ordered" restraint or seclusion initiated by medical or mental health staff as a therapeutic intervention when there are clinical concerns requiring intervention.

There remains a great amount of controversy regarding the empirically validated psychological effects of segregation and what effects, specifically, this has on individuals with or without serious mental illness. In sum, it appears that prolonged segregation exposes individuals to potential psychological, physiologic, and medical risks. Those with SMI have a special vulnerability to the adverse effects of social isolation. Psychiatrists should assist correctional systems with the development of evidence-based behavioral interventions that avoid the potential harm of social isolation.

The NCCHC Standard broadly defines segregated inmates as “those isolated from the general population and who receive services and activities apart from other inmates.” These housing units can be labeled as “administrative segregation, protective custody, disciplinary segregation, or a supermax tier.” It notes that “for the purposes of this standard, the living and confinement conditions define the segregated status, not the reason an inmate was placed in segregation.” The NCCHC Standard has an additional category—“extreme isolation”—which “refers to situations in which inmates are seen by staff or other inmates fewer than three times a day.”

The APA Guidelines state that when an inmate is segregated for any reason from the general population, the responsibility to address serious mental health needs remains in effect (Table 58.3–7). Indeed, because of the stressful nature of segregation housing, facilities should make special efforts to assess and address mental health treatment needs in these settings. Although correctional psychiatrists should not be involved in the decision to place an inmate in disciplinary segregation, once an inmate is there, the psychiatric staff should monitor their mental health status because an inmate who is placed in and is unable to cope with administrative segregation or other specialized single-cell housing assignment might also be at increased risk of suicide.

Table 58.3–7.
The American Psychiatric Association Guidelines on Principles for Mental Health Services in Segregation Housing

The APA Guidelines recommend that in providing essential mental health service in segregation housing, the following principles should be observed:

- Inmates should be placed in segregation housing solely for correctional purposes and never because they exhibit the symptoms of mental illness, unless there is an immediate and serious danger for which there is no other reasonable alternative. (This principle does not refer to medical or psychiatric seclusion, which should follow state mental health law and professional practice.)
- When an inmate is placed in segregated housing for appropriate correctional reasons, the facility remains responsible for meeting all of the serious medical and psychiatric needs of that inmate. Thus, such inmates must receive any mental health services that are deemed essential, and require closer monitoring of psychiatric decompensation than in general population.
- Inmates who are in current, severe psychiatric crisis, including but not limited to acute psychosis and suicidal depression, should be removed from segregation until such time as they are psychologically able to tolerate that setting.
- Inmates who are known to have serious mental health needs or a history of one, when housed in segregation, must be assessed on a regular basis by qualified mental health practitioners to identify and respond to emerging crises at the earliest possible moment.
- Institutions should provide for regular rounds by a qualified mental health clinician in all segregation housing areas, and each inmate should be visited briefly to assess any emerging problem. The clinician should communicate with segregation security staff in order to identify any inmate who appears to be showing signs of mental deterioration or psychological problems.

Similarly, the NCCHC recommends, “inmates who are seriously mentally ill should not be confined under conditions of extreme isolation.” The Commission adds, “policies should also address how vulnerable populations like an adolescent, older adults, pregnant or mentally ill inmates are managed in segregation. Since segregation can exacerbate pre-existing conditions, staff should be extra cautious when placing vulnerable inmates in segregation." Similar position statements have been published by the APA (2017), and the SCP (2013).

Institutional Transfers. Classification committees continuously juggle custody and medical classifications of inmates with their workforce requirements and available space. Most institutions provide a list of the next day's transferees to the correctional psychiatric staff so that they can assemble the inmate's mental health records. Correctional psychiatric staff should ensure that the receiving unit has the requisite psychiatric resources to continue to meet the patient's needs. Each facility should have a policy that allows psychiatric staff to put a psychiatric hold on any interunit transfer of an inmate. Decisions regarding admission to and discharge from inpatient facilities are the sole provinces of clinicians.

Disciplinary Hearings. As a rule, correctional psychiatric staff should not participate in disciplinary hearings and should never be part of the punishment decisions. However, there are occasions when information from psychiatric staff might be helpful in protecting the inmate from inappropriate discipline. For example, a schizophrenic patient might refuse to comply with a correctional officer's directions because of negativism rather than defiance.

Discharge Planning. Studies of recidivism among persons in the justice system with mental illness indicate that effective discharge planning is essential to the continuity of care and a critical part of adequate psychiatric treatment in jails and prisons.

Despite court interventions developed for detainees with mental illness, there is still a lack of coordination and continuity of care for such persons on release. After incarceration, former inmates with mental illness have residential, financial, health, and mental health needs. Face-to-face linkage with community services has the greatest likelihood of success. Because most jails cannot control the court's release decisions, they usually do not know when an inmate is to be released, and so most jails do not provide case management or discharge planning services. To provide such services, discharge planning must start at admission. Providing uninterrupted medications after release is an important challenge. Without psychiatric medications, recidivism is almost inevitable.

As the APA Guidelines state, “Timely and effective discharge planning are essential to the continuity of care and an integral part of adequate mental health treatment.”

This is true whether the patient is being released into the community or transferred to another correctional facility. Because discharges (e.g., from jails) or transfers (e.g., between prisons) can occur on short notice, it is recommended that discharge planning be a part of the initial treatment plan. Essential services that should be included in adequate discharge planning are psychiatric assessments, appointments to be arranged, notifications, staff responsibilities, linkages to community-based services, help with the obtaining of necessary financial benefits (e.g., Medicaid) and housing (due to the high incidence of homelessness in the jail and prison populations), placements, and appropriate linkages.

The NCCHC Standards suggest a number of components for a discharge-planning program:

- Formal linkages between the facility and community-based mental health organizations
- A list of community-based mental health providers that is used for referral
- An inmate education session that emphasizes the importance of follow-up aftercare
- Arrangement for follow-up mental health services before an inmate’s release
- Preparation of mental health summaries
- Assistance to inmates with their application to entitlement programs
- If appropriate, a supply of medications provided at the time of the inmate’s release

Reentry Programs. Whereas discharge planning is an aspect of services in jails and prisons, the last few decades have seen the proliferation of reentry programs, which can provide discharge planning and transition services to people with mental illnesses being released from city jails or state or federal prisons. These programs (usually government-funded—generally state or county) evaluate, select, and then actively link (and follow-up) the inmate with mental illness reentering the community to a wide variety of services, including intensive case management, mobile services, outpatient treatment, psychiatric rehabilitation, housing, vocational and educational services, access to entitlements, family supports, and substance abuse treatment.

This important area of reform of the correctional system gained added impetus from the Second Chance Act of 2007, federal legislation designed to ensure the safe and successful return of prisoners to the community by providing the following: Grants to states and local governments to promote the safe and successful reintegration into the community of individuals who have been incarcerated, including employment services, substance abuse treatment, housing, family programming, mentoring, victims services, and methods to improve release and revocation decisions using risk-assessment tools; grants to nonprofit organizations that can be used for mentoring adult offenders or offering transitional services for reintegration into the community; grants to improve the availability of drug treatment to offenders in prisons, jails, and juvenile facilities; and grants to states, local governments, and Indian tribes to develop and implement family-based treatment programs for incarcerated parents who have minor children. It also authorizes the U.S. Justice Department's National Institute of Justice and the Bureau of Justice Statistics to conduct reentry-related research and establishes a national resource center to collect and disseminate best practices and to provide training on and support for reentry efforts.

In a 2007 Task Force report by the American Psychiatric Association's Task Force on Outpatient Forensic Services, several barriers to successful re-entry following incarceration are identified; these included significant social isolation and stigma related to both mental illness and justice involvement; additionally, loss of social benefits such as SSI/SSDI, difficulties seeking housing, and the severe shortage of outpatient psychiatric services. Such gaps in access further contribute to the risk of recidivism and reincarceration among those released to the community without adequate supports.

Several types of programing have been proposed to aid in successful re-entry and reduce the risk of repeat justice involvement. Two examples include Forensic Assertive Community Treatment (FACT) and Critical Time Intervention (CTI). FACT aims to reduce rates of recidivism by engaging high-risk individuals with histories of justice involvement, increasing engagement in care through proactive outreach and wrap-around services. In contrast, CTI represents a 9-month, staged intervention that promotes individuals being linked to community services and support agencies. It has been shown to be effective at facilitating treatment engagement at the time of release from psychiatric hospitals and shelters, and the intervention has also been described as a promising model for facilitating re-entry from prisons for individuals who have a mental illness.

Each year correctional facilities release approximately 12 million inmates. Because society inevitably shoulders the cost of their treatment, the period of incarceration is an opportunity to create an infrastructure to identify and treat these patients. Effective correctional psychiatric systems will have a positive influence on the public's mental health. So, in recent years, it has become increasingly evident that correctional psychiatry must be considered an integral part of community psychiatry and that correctional health must be conceptualized as an important aspect of public health.

Additional Treatment Considerations and Special Populations

Women in Correctional Facilities. Although the number of women in jails and prisons is relatively small compared to the number of men, their percentage of the total correctional population is rising. Thus, at year-end 2006, women made up 7.2% of the population under state or federal jurisdiction, up from 6.7% in 2000. Until recently, most psychiatric treatment programs for women have been based on treatment models designed for men. It is now recognized that female inmates require very different screening, evaluation, and treatment, and with the reform of the correctional system, treatment programming provided to women in jails and prisons is changing dramatically.

As noted in the APA Psychiatric Services in Correctional Facilities, 3rd Edition: Female inmates frequently encounter different stressors before, during, and after incarceration than their male counterparts. More than 75% of women entering correctional settings report a history of emotional, physical, or sexual abuse as a child or adult. They have higher rates of domestic violence victimization than men. One aspect of this change is the recognition that female inmates have had high rates of victimization (sexual and physical), causing PTSD. The trauma of being raped before 16 years of age was the most frequently reported antecedent of PTSD among female prisoners. Such prevalence of trauma requires that a trauma-informed lens be applied to the provision of care in correctional settings, as well as to the utilization of potentially traumatizing interventions such as seclusion and restraint.

Demographic studies have shown that compared to men, a greater percentage of women entering a jail or prison have a serious and persistent mental illness. Although the rates of bipolar disorder and schizophrenia are similar for incarcerated men and women, a much larger percentage of women are diagnosed with major depression and severe anxiety disorders, especially PTSD. In addition, a higher percentage of women than men in jails and prisons enter these settings with a history of substance abuse.

Programming for women in correctional facilities must also consider that most women in correctional settings have dependent children and at least one child for whom they have been the primary caregiver. Their concerns about their children require special counseling on parenting and perhaps child custody. It is additionally important to attend to the health and mental health care of women who are pregnant or who have given birth recently. The correctional psychiatrist should be alert for and should minimize the risks associated with peripartum depression and psychosis, other adjustment disorders, and distress, and ensure that the facility establishes a policy that a comprehensive mental health evaluation be conducted or has any mental health problems during the pregnancy, delivery, or postpartum period.

Table 58.3–8.
American Psychiatric Association Position Statement on Treatment of Substance Use Disorders in the Criminal Justice System (2016)

1. Consider drug court and similar alternatives whenever they may be viable options to divert individuals from the criminal justice system.
2. All inmates should be screened by trained professionals and assessed for the presence of substance use disorders, withdrawal symptoms, and comorbid psychiatric illness, in addition to Hepatitic C, tuberculosis, and HIV.
3. Treatment for the above should be available within correctional facilities, or alternatively the ability to arrange timely transfer to an appropriate medical facility should be available. Health professionals should be able to screen for withdrawal.
4. Pharmacologic therapies, relapse prevention strategies, and psychotherapy for substance use disorders should be available for arrestees and inmates with substance use disorders.
5. Probation or parole should be conditional on receiving treatment for the substance use disorder whenever appropriate and clinically recommended. Furthermore, community treatment resources and access to care should be ensured upon release.

Data from American Psychiatric Association. *Position Statement on Treatment of Substance Use Disorders in the Criminal Justice System*. American Psychiatric Association; 2016.

Inmates With Substance Use Disorders in Correctional Facilities. The correctional psychiatrist must have knowledge and familiarity in the assessment and treatment of incarcerated individuals with substance use disorders because it is estimated that up to 70% to 90% of offenders have a substance use disorder at the time of their entry into the criminal justice system, and criminal behavior often occurs when an individual is under the influence of alcohol or other drugs. Furthermore, notably, some serious suicide attempts and completed suicides in jails may occur within the first 24 to 48 hours of admission and are often carried out by inmates who are either intoxicated or experiencing withdrawal symptoms. In 2016, the APA Assembly and the APA Board of Trustees approved a revised position statement prepared by the APA Council on Addiction Psychiatry on the treatment of substance use disorders in the criminal justice system, as shown in Table 58.3–8.

INMATES WITH CO-OCCURRING DISORDERS IN CORRECTIONAL FACILITIES. In 2006, the Bureau of Justice Statistics stated that about 74% of inmates in state prisons and 76% of jail inmates who had a mental health problem also met the criteria for substance use disorder. Nearly 63% of state prisoners who had a mental health problem had used drugs in the month before their arrest, compared to 49% of those without a mental health problem. For the correctional psychiatrist, the nondetection of one or more co-occurring disorders in jails and prisons risks the exacerbation of any behavioral problems and elevates the risks of suicide and poor outcomes in treatment.

For these reasons, the APA Guidelines recommend that the detection of one type of disorder (i.e., substance use or mental illness) immediately triggers an investigation into the other type of disorder. The importance of a coordinated system of screening, referral, assessment, and diagnosis for co-occurring mental health and substance use disorders is that one type of disorder can mimic the other, interfere with detection of the other, or overshadow the other type, and one type might affect the presentation of the other type of disorder. Table 58.3–9 lists the recommended APA Guidelines strategies for inmates with co-occurring disorders.

Table 58.3–9.

American Psychiatric Association Guidelines on Recommended Strategies for Inmates with Co-Occurring Disorders

Services must integrate treatment that addresses the person’s mental health and substance use disorders simultaneously.
Each type of disorder must be treated as a primary disorder, with a focus on understanding how they interact with each other.
Medication must be prescribed with caution. In individuals who are not on psychotropic medications, they should be fully allowed to detoxify from substances before starting medications unless psychotic or suicidal symptoms are present.
Psychosocial problems and skill deficiencies should be addressed with individualized programming.
Treatment should be integrated with self-help groups and support networks, which may be invaluable tools in assisting treatment participants in maintaining their commitment to daily alcohol and drug abstinence.
Interventions must be designed for the particular setting, each setting requiring differing intensity, length, and types of services.
The presence of co-occurring disorders requires special attention to discharge planning, which must address housing and job needs, family reconnection, and continued treatment.

The APA Guidelines emphasize that substance abuse services should be integrated with mental health services and that psychosocial problems and skill deficiencies should be addressed with individualized programming created through comprehensive assessment and consultation with the inmate’s clinician, family (or significant others), and correctional medical and mental health clinicians.

In contrast to the APA position recommending the integration of services, the NCCHC in its standard on Substance Abuse Services relegates the roles of the medical and mental health staff to referral:

> *Increasingly, in larger correctional systems, inmates with [substance use] . . . disorders are receiving treatment for these problems from specialized treatment providers. Substance abuse counselors who treat [substance use] . . . problems should be properly qualified to do so by a recognized accrediting body. Medical and mental health care*

providers can facilitate the treatment process by referring inmates for treatment, providing counseling to motivate inmates to receive treatment, legitimizing self-help groups, tailoring controlled substances prescribing practices, and otherwise being a partner in the process of treatment.

There is an agreement, however, that inmates with co-occurring mental illness must not be barred from participation in substance abuse treatment programs and that self-help, 12-step, and peer support groups and networks play an important role in the rehabilitation of abusers of alcohol and other drugs in the correctional system.

DETOXIFICATION. When psychotropic medications are required during detoxification to manage medical or prevent impairment and sequelae, agitation and symptoms, or agitation, a physician must be responsible for managing the detoxification process.

Prescription of benzodiazepines might be useful to prevent or attenuate withdrawal symptoms and detoxify the inmate. However, their use should be short-term and on a tapering dose schedule to ensure that the prescribed medication does not serve as a substitute for the substance of abuse.

When circumstances warrant, an inmate should be detoxified or free from substance use for a reasonable period of time before psychotropic medications are prescribed unless psychotic or suicidal symptoms are present. The opiate- or other substance-dependent pregnant female presents special challenges to correctional systems, and a review of NCCHC standards and other accepted practice guidelines is recommended.

Inmates with Intellectual and Developmental Disabilities in Correctional Facilities. Offenders with co-occurring mental illness and intellectual or developmental disability encounter unique difficulties in the criminal justice system and have special treatment needs. From 4% to 10% of inmates have an intellectual developmental disorder (formerly referred to as mental retardation or borderline intellectual functioning), that is, significantly subaverage intellectual functioning and impairments in adaptive functioning, and “it is estimated that 40% to 70% of individuals with mental retardation in jails and prisons have diagnosable psychiatric disorders.”

This is a substantial number of inmates in the correctional population who have intellectual disabilities that present special problems for the correctional psychiatrist. According to the APA Psychiatric Services in Correctional Facilities, inmates with an intellectual or developmental disability and co-occurring mental disorders are unfortunately the most likely to be victimized by other inmates. Furthermore, custody and treatment staff need additional training and education on intellectual and developmental disabilities to lessen the likelihood that they misperceive behaviors as intentional rule infractions or attribute them solely to intellectual disability while an SMI goes untreated.

Geriatric Inmates in Correctional Facilities. The Federal Bureau of Justice Statistics notes that the U.S. prison population is aging and that "expressed in terms of percent change, the oldest age group, inmates age 55 or older, recorded the largest change—an increase of 85 percent since 1995." Effective access to mental health services for older inmates requires recognition of the special challenges facing inmates and mental health professionals, especially as the number of offenders older than 65 years in state and federal prisons increased at 94 times the rate of the overall sentenced population between 2007 and 2010. The aging of the correctional population will be a major problem in the 21st century.

As noted by the APA Guidelines, for the correctional psychiatrist, older inmates have medical needs that sometimes might present with psychiatric symptoms and might complicate psychiatric intervention in terms of medication, relevance of counseling, structure of time (programming) of the inmate, and housing. These problems are more likely to be chronic, permanent, and progressive, might be related to the possibility of dying in custody, and might be expensive (Table 58.3–10).

For the older inmate, the isolation can be expressed in a variety of ways and, when extreme, can exacerbate or create mental illness or psychiatric crisis. Special issues are related to (1) acceptance after release from incarceration, (2) provision of food, shelter, and clothing after release, (3) assault and potential greater sequelae of injury, and (4) isolation from older, "free" relatives and friends who might be unable to travel to visit.

Table 58.3–10.
The APA Guidelines on Psychosocial Concerns of Older Inmates

Lack of connection to or interaction with other inmates in the general population, given the relatively small (though increasing) percentage of older inmates
Physical vulnerability to more serious consequences of assault
More difficulty and greater length of time to adjust to a new environment
Higher rate of completed suicide
Greater possibility of dying during incarceration
Higher incidence of loss of external supports, for example, spouse, parents, friends, and other external supports

Some of these issues might benefit from mental health intervention, including group or peer counseling. Psychiatric and clinical staff need training in the special needs and care required by older inmates, and they can help educate custody staff to recognize and deal with cognitively impaired inmates who might not respond appropriately to a direct order, mobility issues, and those who might demonstrate early confusion and cognitive impairments and associated sight and hearing impairments.

The Dying Inmate. Facilities should have written policies and training to address the in-custody dying inmate–patient. When feasible, the care of an inmate with terminal illnesses should involve the use of a hospice approach—a facility that emphasizes providing support and humane care to a dying patient rather than trying to cure the underlying disease. This might be inside the prison (less likely to be needed in jail) or a contract facility outside of the prison. Another consideration is the use of compassionate release (also called “medical parole”), which is available in a majority of states. Compassionate release can have a number of advantages, including cost savings for the prison health care system, which can be substantial.

The use of inmate volunteers (peer trainers) who are oriented on basic health issues, universal precautions, and mobility management can reduce the dying inmate–patient’s (or their family’s) perception that “the prison isn’t doing enough.” Group therapy, realistic planning, and suicide prevention are specific interventions that the psychiatrist should either provide directly or ensure provision by other mental health professionals.

The policy of “compassionate release” refers to the ability of institutions to grant early release or parole to individuals suffering from severe illness while incarcerated; these policies are based on the recognition that in cases of severe illness, appropriate treatment is difficult, if not impossible, to achieve in correctional settings. As the older adult population within the correctional system has continued to grow in recent years, the policy of compassionate release has become increasingly relevant. However, very few individuals are successfully granted release under this policy. Ensuring evidence-based palliative care and compassionate preservation of dignity have been cited as important considerations among medical professionals advocating for the value of compassionate release programming.

Rape and Victims of Sexual Assault. A full description of the psychiatric assessment and prevention of sexual abuse and exploitation within the correctional setting is beyond the scope of this chapter. The following provides a summary overview.

In 2003, the Prison Rape Elimination Act (PREA) became federal law; however, this phenomenon continues to be a challenge to manage with regard to prevention and aftercare. The Bureau of Justice Statistics report for the year 2007 indicated that an estimated 60,500 inmates (or 4.5% of all state and federal inmates) experienced one or more incidents of sexual victimization involving other inmates or staff. Additionally, among the 146 prison facilities in the 2007 National Inmate Survey (NIS), which was conducted in 146 state and federal prisons between April and August 2007 with a sample of 23,398 inmates, six had no reports of sexual victimization from the sampled inmates, and 10 had an overall victimization rate of at least 9.3%.

The national PREA standards were released in 2012. There is now a need for compliance with this federal mandate for facilities in the fields of adult, juvenile, and community corrections. Both correctional staff and health care staff might need education, training, and psychological support in managing either victims or perpetrators of sexual assault. Both the NCCHC and the American Correctional Association (ACA) play a vital role in supporting correctional institutions in the implementation of and compliance with the health care aspects of the PREA with education, curriculum developments, and technical assistance. Specialty training on complicated PREA issues is available for the psychiatrist and medical and mental health care practitioners. The curriculum includes information on detecting and assessing signs of sexual abuse and harassment, medical forensic examination and forensic evidence preservation, and effective and professional responses and reporting. In August 2013, the U.S. Department of Justice began auditing facilities to ensure compliance with the Act.

Inmates Serving Life Sentences. Psychiatrists may encounter inmates with one or more life sentences, life without parole, referred to as “lifers.” These individuals pose a unique challenge to the correctional psychiatrist. Because these individuals will not be released from prison, many usual incentives such as parole, token incentives, and the like have less effect.

The APA Psychiatric Services in Correctional Facilities notes that “inmates draw on many resources to assist their adaptation to incarceration, such as family contact, peer support, work, education, and spiritual pursuits, including the practice of faith-based traditions.” Some individuals may lack these psychosocial resources such as no regular family contact, no visitors, no one on their visitation lists, no one to help fund their commissary purchases, family estrangement, and the like.

Inmates on Death Row. The care of “Death row” individuals, inmates housed on death row, who are awaiting exhaustion of legal appeals, or whose legal appeals are exhausted, poses a myriad of complicated clinical, ethical, and legal questions. Some examples of issues include the death row psychiatric assessment, considering “justifiable” depression, suicide risk management, individuals on death row who require psychiatric hospitalization, psychiatric treatment thereby restoring one’s competency to be executed, and how to balance ethical/role boundaries between clinical and forensic work. Because of the lengthy appeals process and high stakes involved, mental illness and intellectual disabilities are commonly raised in postconviction proceedings, typically on Eighth Amendment claims (arguing that the execution of the mentally ill and/or mentally retarded constitutes cruel and unusual punishment).

Inmates with mental illness on death row present unique and complex ethical issues. Because the participation of a correctional psychiatrist in an execution would violate the principle of *do no harm*, Annotation 4 of

Section 1 of the APA's Annotations states that "a psychiatrist should not participate in a legally authorized execution." Much has been written about the interpretation of the word "participate," and it is clear that the medical community is unanimous that any action that would further the implementation of an execution is prohibited. Furthermore, there is no doubt that this applies to evaluations of competency to be executed. However, what about the treatment of an incompetent inmate to achieve competency? This is a controversial area, and whereas in general, the correctional psychiatrist is obliged to provide treatment to patients in need to relieve suffering regardless of the subsequent nonclinical consequences, it has been suggested that physicians who are opposed to the death penalty not practice on death row. Similarly, it was held in the case of *State v. Perry* that the patient retains the right to refuse treatment and the state cannot treat over objection so as to impose the death penalty.

The NCCHC Standard "Inmate Executions" states that "Mental health staff does not participate in inmate executions" and sets out the following compliance indicators:

> *An inmate's treating clinician does not provide a competency evaluation for execution.*
>
> *Mental health services staff members do not assist, supervise, or contribute to the ability of another individual to directly cause the death of an inmate.*
>
> *Mental health staff members provide ongoing mental health services to inmates in death row as clinically indicated according to individual treatment plans.*

It is noted that the intention of this standard is that mental health staff not be involved in any action that would directly cause the death of an inmate because such involvement in inmate executions poses an ethical dilemma: "In order to be effective mental health care providers, correctional mental health care staff must maintain an appropriate professional relationship with their patients. This relationship is lost when mental health care staff assumes a role in inmate executions." The NCCHC Position Statement entitled Competency for Execution recommends that "the determination of whether an inmate is 'competent for execution' should be made by an independent expert" and not by correctional psychiatric staff.

Lesbian, Gay, Bisexual, and Transgender Persons and Gender Dysphoria. According to the APA Psychiatric Services in Correctional

Facilities, trauma and stigma experienced by lesbian, gay, bisexual, or transgender (LGBT), individuals can increase their psychological distress and decrease their willingness to seek mental health services. When incarcerated, they risk additional discrimination and abuse. Compared with heterosexual inmates, studies have reported that they have ten times the rate of sexual victimization by other inmates and up to three times the rate of sexual victimization by staff. This risk needs consideration on arrival at any correctional facility. LGBT individuals differ in degree of comfort with their sexual orientation or gender identity and whether they are “out” or “closeted.” Their choice about disclosure can change when moving from the community to jail or prison and between institutions. A respectful and nonjudgmental approach by the correctional psychiatrist can help LGBT inmates explore their choices and cope with their concerns. Transgender inmates, for example, may feel distress when housed in settings that do not allow them to express their gender identity or when they elect to stay closeted because of safety concerns. A therapeutic relationship in which they feel known by someone safe can improve emotional well-being.

The evaluation and treatment of gender dysphoria, formerly known as gender identity disorder, is a particularly challenging area. The evaluation, treatment, and decision-making processes of whether to continue, discontinue, or initiate hormonal treatment for offender patients are complicated, and even more so due to PREA audits and enforcement in corrections. Custody leadership makes decisions regarding classification, housing, transportation issues, and whether they allow access to gender-preferred clothing, toiletries, and housing assignments. Beyond hormonal treatment, many correctional systems do not have uniform policies about permissible treatment for transgender inmates. However, more recently, the courts have been ruling in favor of cases by inmates calling for sex reassignment surgery in the correctional setting, with some courts agreeing that denying such a surgery is a violation of the Eighth Amendment. Consistent with the prevailing position of professional medical organizations, including the APA, courts, and society in general, are increasingly recognizing gender dysphoria as a medical condition appropriate for treatment. The California Department of Corrections and Rehabilitation is credited as the first state system in the country to have implemented policies granting these surgeries.

Hunger Strikes in Jails and Prisons. Hunger strikes (the refusal of nutrition as a means of passive resistance) are a daunting problem in jails and prisons. Although the history of hunger strikes goes back at least to the Roman Empire and in the Western world, there is generally a right to go on a hunger strike that is protected as a matter of “privacy” or a “liberty interest” or can be regarded as an expression of free speech, clearly, in a correctional facility other factors come into play. Correctional authorities are charged with the “care and custody” of the inmates. Therefore, the following principles should apply:

- The correctional facility must provide for the evaluation of the situation for treatment if necessary and perhaps for legally allowable intervention.
- The medical services must provide for the evaluation of the medical stability of the inmate.
- The correctional psychiatrist must be available to evaluate such an inmate’s psychiatric condition and whether there is a need for treatment.
- The correctional psychiatrist must also evaluate the motivation for the hunger strike and the inmate’s capacity to understand the consequences of their actions and the medical decisions being made.

The majority of U.S. courts that have considered the question hold that an order to force-feed does not violate a hunger-striking prisoner’s constitutional rights because the institution in which the inmate is housed is responsible for his care while incarcerated, and there are other compelling governmental interests, such as the preservation of life, prevention of suicide, and enforcement of prison security, order, and discipline, that outweigh any constitutional rights asserted. It is interesting to note, however, that international authorities argue to the contrary. International courts have tended to allow hunger strikes to proceed even to death or disability. Thus, forced feeding of prisoners is prohibited by the Tokyo Declaration of 1975 by the World Medical Association and affirmed in 1992 by the Declaration of Malta.

In 1994, the ACHSA adopted a Position Statement that allows forced feeding when the legal procedure for medication over objection has been followed:

The management of a hunger-striking prisoner presents an ethical conflict between the obligation to preserve life and relieve suffering on the one hand and the obligation to respect patient autonomy on the other. Correctional health care providers should make every reasonable effort to honor patient self-determination. However, the deprivation of freedom that incarceration imposes will affect decision-making of the inmate patient. Therefore, special efforts in patient education and counseling are indicated.

Since forced feeding is a form of involuntary treatment, the responsible medical authority must seek the consent of the court or a legally appointed guardian, following the local requirements for involuntary treatment. The physician should make it clear to the court and to all others concerned; however, that ethical medical conduct in this setting demands medical intervention to preserve life from actions that are self-destructive.

ACHSA members should give careful consideration to the development of policies and procedures that provide a responsible and compassionate approach to the hunger-striking prisoner and which make it clear that efforts will be made to intervene with forced feeding in order to save a life.

The APA Psychiatric Services in Correctional Facilities recommends the following:

> *Hunger strikes are considered a medical emergency, and psychiatrists are often asked to evaluate inmates to determine if they have the mental capacity to make an informed decision regarding continuation of the hunger strike. Psychiatrists can perform evaluations to rule out underlying mental illness as a cause of the hunger strike (e.g., suicidal depression or delusions regarding prison food).*

There is currently no consensus to guide psychiatrists in the United States on the ethical standards of force-feeding to end hunger strikes in correctional facilities. Although the World Medical Association and the AMA, with limited exceptions, have taken stands against the practice, the Supreme Court of Connecticut, in *Commissioner of Correction v. Coleman* (303 Conn. 800 SC 18721 [2012]), found that the state's interest in the inmate's health and legitimate penologic interests in the safety of the facility outweighed the inmate's right to autonomy. Furthermore, the court ruled that "force-feeding did not violate constitutional rights to free speech and privacy."

THE FUTURE OF CORRECTIONAL PSYCHIATRY

In light of the significant numbers of individuals in our nation's jails and prisons, and due to the significant burden of mental illness and psychiatric needs in this vulnerable population, future directions for correctional psychiatry involve developing policies and protocols to ensure equitable treatment and access to care.

Diversion and Community-Based Interventions

There have been increasing efforts to pursue alternatives to incarceration of persons with severe mental illness and substance abuse disorders. One of the most promising alternatives is the diversion model, designed to prevent or minimize detention of the nonviolent mentally ill and to divert persons with severe mental illness to appropriate community-based mental health services in lieu of incarceration.

Interventions may occur at various points of interaction between individuals with mental illness and the justice system (Fig. 58.3–5). Pre- and postbooking diversion programs may hold promise for addressing overcrowding in jails and prisons and ensuring that individuals with mental illness are directed toward treatment.

Prebooking programs involve the utilization of first-response programming to respond to crises in the community. Examples might include specialized police response teams, mental health professionals hired by police departments, and local mental health crisis teams who often have relationships with local police departments. Other prebooking interventions might include collaboration between the above entities as well.

Postbooking interventions can be jail-based, involving recognition and assessment of detainees with mental health needs so that they can be transitioned to a community-based treatment program. In contrast, court-based diversion might involve assessments performed by courthouse clinicians who perform assessments and engage in discussion with the prosecution, defense, and a judge to advocate for release dependent on adherence to a community treatment protocol. Some individuals may be seen in specialized mental health courts, where involved individuals have specialized training in mental illness and will connect the individual to treatment, with follow-up to ensure adherence to the mandated treatment program.

Assisted outpatient therapy (AOT), also known as “outpatient commitment,” is also being studied and implemented to address the burden of serious mental illness in the community and in institutions. To date, 47 states have approved AOT programming (Connecticut, Maryland,

and Massachusetts are the three states that do not currently have AOT). AOT represents a means through which court-ordered treatment can be coordinated for patients with severe mental illness who have experienced recurrent hospitalizations, poor adherence to recommended treatment, and/or significant adverse consequences (such as violence or justice involvement) because of their mental illness. While principles of patient autonomy and beneficence undeniably necessitate continued efforts to engage patients in voluntary treatment, there are individuals who, due to severe mental illness, are unlikely to voluntarily engage in treatment for whom court-mandated treatment programs might be effective in reducing risk for adverse outcomes. In a revised position statement by the APA regarding these programs, it was recognized that involuntary outpatient commitment and AOT could be effective at promoting recovery when implemented systematically and for a sustained period of time, involving linkage to medication management and psychosocial services with proactive treatment models similar to those of assertive community treatment or intensive case management programs. The APA additionally recommends clear and consistent planning regarding consequences of treatment nonadherence in addition to ensuring that separate review and approval are obtained prior to consideration of involuntary medication administration in the community.

Education

In 1996, the Accreditation Council on Graduate Medical Education (ACGME) recognized the subspecialty of forensic psychiatry, which includes substantial correctional components. The didactic curriculum for the forensic fellowship training requires that the “psychiatric curriculum includes the . . . evaluation and treatment of incarcerated individuals,” and the “clinical experience must include experiences in the . . . treatment of persons involved in the criminal justice system.” In addition, “Clinical placement must provide [forensic fellows] . . . with experience in the evaluation and management of acutely and chronically ill patients in correctional systems such as prisons, jails, community programs, and secure forensic facilities.”

However, though most psychiatrists do not choose to dedicate their careers to forensic psychiatry, the prevalence of justice involvement among individuals with serious mental illness necessitates all providers to feel comfortable managing the unique needs of this population. Despite the number of individuals receiving mental health care in correctional settings and despite the fact that many of these individuals will eventually transition their care back to community providers, only one-third of psychiatry residency training programs included a mandatory correctional rotation for all trainees. Furthermore, even in programs offering elective rotations in correctional psychiatry, very few residents elected to participate. As the field of psychiatry works toward meeting the immense mental health needs of individuals in jails and prisons, increasing trainee exposure to and awareness of correctional psychiatry will be crucial in developing solutions to this public health issue.

Using Technology in Corrections: The Electronic Medical Record and Telepsychiatry

Many county, state, and federal correctional systems have moved toward the implementation of correctional EMR systems. This is particularly helpful in multisite systems or high-volume intake facilities with rapid turnover, or alternatively in large systems where there is common movement, transfers, and turnover of inmates both intra- and intersystem. Thorough medical documentation is useful protection against litigation to help clarify an individual’s assessment and treatment plan and to ensure continuity of care.

Telepsychiatry is another tool with significant promise in relation to meeting the need for mental health care in correctional settings, with the COVID-19 pandemic highlighting the potential benefits of telepsychiatry. Greater comfort by correctional psychiatrists and other mental health professionals with this technology increases the accessibility of expeditious services for patients, and due to less need for off-site transport for psychiatric evaluation, this technology reduces the cost and burden on staff to travel with an offender. More recent evidence has demonstrated the feasibility and efficacy of telepsychiatry in correctional settings. Furthermore, recent legislation in some states requires payment parity for virtual psychiatric encounters, further increasing the sustainability of virtual care in correctional settings. Despite its promise, challenges associated with the use of telehealth technology may include difficulties with rapport building, lack of trust between patient and provider, decreased efficiency of communication, and lack of provider awareness of facility events contributing to the individual's presentation and treatment.

Advocacy

A confluence of forces is accelerating the reform of the correctional system to the benefit of correctional psychiatrists and their patients. Intense advocacy efforts, especially by family members of persons with serious and persistent mental illness in the criminal justice system, through patient advocacy groups such as the National Alliance on Mental Illness and Mental Health America, are becoming increasingly effective in lobbying legislatures to increase mental health funding, staffing, and psychiatric services in jails and prisons.

Advocating around improving mental health laws in each state is an important way to reduce the incarceration of the mentally ill. Mentally ill individuals engage in violence in rare instances. However, when they do, it is frequently in the setting of acute untreated mental illness and substance use. Because the treatment does not always follow the patient outside of hospital walls, building treatment programs monitored and supported by courts in lieu of jail time can be an important way of protecting the autonomy and freedom of mentally ill individuals and reducing the time they are in a locked setting. Better laws that support mentally ill individuals receiving proper treatment also destigmatizes both psychiatric illness and its treatment. The Treatment Advocacy Center is promoting research in this area to help the public better understand mental illness, the pathways to incarceration for the mentally ill, and solutions, through treatment, to reduce the institutionalization of this vulnerable population.

Last, the APA is joining with other professional groups to develop programs and priorities for legislative action, including such groups as the Campaign for Mental Health Reform and the Mental Health Liaison Group. This has, in turn, drawn the attention of county and state governments not only in terms of the requirements of the humane aspects of care and treatment and concerns about litigation but also the financial and societal benefits of preventing mental illness-associated recidivism through jail and prison mental health programming, diversion programs, drug courts, and mental health courts, jail-based and other competency restoration programs, and well-developed reentry programs.

ACKNOWLEDGMENT

This chapter represents an update and revision of previous chapters in this series, most recently by Henry C. Weinstein, MD and Joseph V. Penn, MD from the last edition. We are indebted to Drs. Weinstein and Penn for their work and retain much of their prose in this current edition.

History of Psychiatry

EDWARD SHORTER, PH.D., F.R.S.C.

Motto: “In the natural sciences old views and interpretations of observations are overtaken by new discoveries and retain historical interest only; in the humanities this is never quite the case. Psychiatry has one foot in each of these disciplines and our heritage is not something we can simply leave to the historians.” Julius Hoenig (1981). (Hoenig J. Psychiatric nosology. *Can J Psychiatry.* 1981;26(2):85.)

One of the earliest accounts of mental illness comes from the myths of the Greek gods. Hercules, under a delusive disorder, slays his children, believing them the offspring of another god.

One lad stretched forth his hands, crying, “Oh, dearest father, do not slay me; I am thy son.” But Hercules, “with savage rolling eyes,” as the chronicler tells us, “brought his club down upon the golden-haired head of the boy and broke his skull. The other children and the wife are sacrificed by the same murderous fury.”

The modern reader recognizes the diagnosis of delirious mania, which, like most other psychiatric ailments, is as old as the hills and built into the pathology of the human condition.

Across the millennia, there have been many other accounts of deluded and melancholy patients. Psychiatric illness has always been recognized as medical in nature. Yet psychiatry as a discipline arises only late in the 18th century. It was under the influence of the enlightenment that the prospect of relieving mental illness through institutional care was first broached. There had always been confinement, in the context of the noisome "hospices" that lodged indiscriminately the insane, the poor, the older adults, the medically ill, and the criminal alike. But the concept of dedicated mental hospitals stemmed from the late 18th century, surfacing first in Italy, then in France. In this manner, psychiatry became a specialty, not because its practitioners had special diagnostic or therapeutic skills but because they had the administrative abilities required to run these large institutions. For decades, the emphasis in international surveys of psychiatric facilities would be on architecture and layout rather than on diagnosis and treatment.

Before the late 19th century, there was no such thing as private practice psychiatry. Psychiatry as a discipline was based in mental hospitals, or "asylums"—a term first used in 1766 instead of "lunatic hospital"—and psychiatrists were called "alienists" on the grounds that the distracted mind had become alien. Ambulatory patients were seen in private practice by neurologists or general practitioners.

EARLY BEGINNINGS

The main storyline is the transition from traditional hospices to mental hospitals dedicated to treatment and recovery. Joseph Daquin, a psychiatrist in the Savoyard city of Chambéry, extolled in a work on The Philosophy of Madness (*La Philosophie de la Folie*) in 1792, the bringing of patients "from their fetid holes … to the freedom of a great but enclosed yard. Trained staff will accompany them everywhere and keep them in view; in the yard, warders will let them do whatever they like, simply ensuring that they do not escape, and neither endanger their own lives nor those of others. We will simply let them wander about at will for two hours, or in the interval between one meal and the next." This is not the first description of the therapeutic asylum but certainly the first that extolls the therapeutic advantages of freedom and exercise.

Italy

Most accounts of the history of psychiatry do not begin with Italy, a land that is largely silent on the historical radar. Yet, it was in Florence in the 1780s that modern psychiatry actually began. The key concept is "therapeutic institution," admitting patients in the hope of relieving their distress rather than protecting society from them. The first therapeutic asylum was launched in 1788 when Vincenzo Chiarugi ("KEY-ah-ROO-jee") opened the doors of the old Bonifazio Hospital, previously a typical hospice, exclusively to psychiatric patients. Here, he organized gardens for the patients, provided music, gave a structure to their day, and ensured proper meals and humane treatment. From 1793 to 1794, Chiarugi wrote a three-volume psychiatry textbook based on these experiences, *On Insanity (Della Pazzia)*, specifying that for psychological tranquilization, the patients should be kept in calm, quiet environments: "The sweet songs of gentle, moving music in many cases will represent the first-line treatment." As for stimulating treatments, the patients should undertake moderate exercise in the asylum and at home. In treating melancholy, Chiarugi deemed it "absolutely necessary that … [the physician] finds his way into the patient's heart, gaining his confidence and trust." Chiarugi called this "the psychological treatment" (la cura morale).

Italian psychiatry received a reformist bump-up in 1821 when Antonio Galloni became head of the venerable San Lazzaro Asylum in Reggio Emilia in the north of Italy. Founded in the 12th century as a leprosarium, in the 18th century Reggio Emilia went over to receiving psychiatric patients, and Galloni implemented many of the French reforms (see below), given that Italian psychiatry in these years stood much under the influence of France (later, of Germany). Reggio Emilia's later superintendents included Carlo Livi, who in 1871, at the beginning of his tenure, introduced Italy's first farm colony, and Augusto Tamburini (from 1877, after Livi's premature death), who began outpatient care with local families. Livi and Tamburini were among the leading figures in 19th-century Italian psychiatry, and Reggio Emilia stood as an international model for the villa system—rather than housing inpatients in giant barracks—and for the use of laboratories in patient care. Tamburini's watchwords were “*scienza e amore—studio e benevolenza*” (science and love, research and kindliness).

France

Modern psychiatry was anchored in France in two of the great Parisian hospices that Louis XIV founded in the 17th century: Bicêtre for men and the Salpêtrière for women. The seminal name in French psychiatry is Philippe Pinel, who in 1793 became chief physician of the Bicêtre hospice. Pinel is often seen (in ignorance of the contributions of Chiarugi) as the very founder of psychiatry itself. Yet the contribution of Pinel is difficult to overstate because his Medical-Philosophical Treatise on Mental Illness in 1801 (*Traité Médico-Philosophique sur l’Aliénation Mentale*) became the first international textbook and initiated the centuries-long task (not completed today) of perfecting the nosology of the field. In 1795, Pinel became the chief physician of the Salpêtrière, where he remained until his death in 1826. Pinel is also remembered as an early, influential advocate of humane care, as opposed to the chains-and-beatings approach that earlier characterized asylum life.

Pinel’s student Étienne Esquirol (“ES-kir-ole”), who in 1825, became chief physician of the French national asylum in the Paris suburb of Charenton, is seen as the virtual founder of social psychiatry, assessing social patterns in illness, and further refining Pinel’s nosology (see below). Esquirol inspired the Law of 1838 that obliged each district (department) in France to have a modern asylum; the law became worldwide a model of modern psychiatric care.

The United Kingdom

England. The first therapeutic asylum in England was St. Luke’s Hospital in London, founded by William Battie in 1750. Battie conceived admission to the hospital itself as having a therapeutic character, and in his *Treatise on Madness* (1758), he wrote,

> The regimen [in madness] is perhaps of more importance than in any distemper. It was the saying of a very eminent practitioner in such cases that management did much more than medicine; and repeated experience has convinced me that confinement alone is oftentimes sufficient, but always so necessary, that without it every method hitherto devised for the cure of madness would be ineffectual.

Yet, until the opening of the Maudsley Hospital in 1923, the anchor of English psychiatry was Bethlem Hospital ("Bedlam"), founded in 1247 as a base for the Crusaders, then gradually given over to the care of the insane. (In 1930, the hospital removed from the district of Southwark to suburban Kent, at which time the old building—one of several over the centuries—became the Imperial War Museum.) The hospital is indissolubly linked with the Monro dynasty of psychiatrists, of whom Edward Thomas Monro was in office from 1816 to 1855. Among the hospital's medical officers, or "apothecaries," was John Haslam, author of Observations on Madness and Melancholy (1809), the detailed cases of which are among the earliest patient reports in psychiatry.

In the first half of the 19th century, England led in the international movement to asylum reform, emphasizing "moral treatment" (psychotherapy), which began late in the 18th century at the Quaker Retreat in York, and the "non-restraint" system of patient care (abolishing chains and the like) that John Conolly initiated after he became superintendent of the Middlesex Asylum at Hanwell (a London suburb) in 1839. "The old system," said Conolly in 1856, in his Treatment of the Insane without Mechanical Restraints, "placed all violent or troublesome patients in the position of dangerous animals. The new system regards them as afflicted persons, whose brain and nerves are diseased, and who are to be restored to health, and comfort, and reason."

Scotland. Psychiatry in Scotland was dominated by the Edinburgh Royal Asylum (today the Royal Edinburgh Hospital), founded in 1813 at the Morningside estate, out of dismay at how badly Scottish poet Robert Fergusson was said to have been treated at the London asylum of "Bedlam." (He died there at 24.) The Royal Edinburgh was led over the years by a series of major figures in the history of British psychiatry, such as Thomas Clouston, *whose Clinical Lectures on Mental Diseases* (1883) remained for years the standard textbook.

Ireland. How direly Ireland required modern psychiatry emerges from testimony before the House of Commons in 1817:

> There is nothing so shocking as madness in the cabin of the Irish peasant, where the man is out laboring in the fields for his bread, and the care of the woman of the house is scarcely sufficient for attendance on the children. When a strong man or woman gets the complaints [severe psychiatric illness], the only way they have to manage is by making a hole in the floor of the cabin, not high enough for the person to stand up, with a crib over it to prevent his getting up. The hole is about five feet deep, and they give this wretched being his food there, and there he generally dies.

Until the foundation of the Irish Free State in 1922, Ireland was a colony of Great Britain, and Irish psychiatry rose simultaneously with English psychiatry. The Richmond Lunatic Asylum in Dublin (now St. Brendan's Hospital), the flagship of Irish psychiatry, was founded in 1816, and in 1857, Joseph Lalor became its first resident medical director. Given the absence of psychiatry in the medical curriculum until 1875, the only means of becoming a psychiatrist in Ireland, and in much of Scotland and England, was to serve as an assistant physician in an asylum. Irish clinicians of the day, such as Conolly Norman, a later superintendent of Richmond, favored the strong German emphasis on clinical psychiatry and found unhelpful the anatomical speculations of the era about causation (did the ovaries cause mental disease or not?).

German-Speaking Europe

"If French is the language of diplomacy, then German may be said to be the language of psychiatry," as Edward William Anderson, professor of psychiatry in Manchester, observed in 1962 after German had become a dead language internationally. In the years between 1850 and 1933, German was indeed the language of psychiatry, as it was the language of culture and scientific life in an enormous swath between Budapest (Hungarian psychiatrists all published in German) and Strasbourg, or between Hamburg and Vienna. Unlike England and France, where a single great city dominated the psychiatric life of the country, in German-speaking Europe, there was a profusion of small states and over 30 university psychiatric departments or psychiatric hospitals existed, most of which had scientific aspirations; by 1900, Heidelberg, Berlin, Munich, and Vienna had become world centers of psychiatric learning.

Austria-Hungary. Psychiatry in Vienna was symbolized by the famous Tower of Fools (Narrenturm), a roundish structure with 139 individual cells (that still exists today), built by Emperor Joseph II in 1784 as part of the Vienna General Hospital. Although it was soon overtaken by advances in care, it remained an emblem of the distinctiveness of Viennese psychiatry, which later gave birth to such figures as Sigmund Freud (psychoanalysis) and Manfred Sakel (insulin coma therapy—see below for both).

Germany (After 1871, United as the German Empire). In the early years, German psychiatry tended to be overshadowed by the French. Yet, there were spots of light. An important early figure was Wilhelm Griesinger, who, as an assistant physician to Ernst Albert Zeller in the Winnenthal asylum in the early 1840s, began to propagate the view that "mental disease is brain disease," a main tenet of later German biologic psychiatry. In 1845, Griesinger expressed his views in a textbook, *Mental Pathology and Therapeutics* (*Die Pathologie und Therapie der psychischen Erkrankungen*), a second edition of which in 1861, became the leading international textbook of biologic approaches to the field. In 1865, Griesinger moved from Zurich to Berlin as a professor of psychiatry at the Charité Hospital; here, he founded in 1867 the *Archives of Psychiatry and Nervous Diseases (Archiv für Psychiatrie und Nervenkrankheiten)* that was the equivalent of *the Archives of General Psychiatry* (renamed *JAMA Psychiatry* in 2013) today.

Several reformed psychiatric hospitals flourished in Germany early in the century, including Siegburg north of Bonn, founded in 1825 by

Maximilian Jacobi, who introduced to Germany the “no restraint” system—not shackling patients—and forms of psychotherapy. These reformed asylums also constituted centers of research as well as humane care, and in the days before the shift of scholarship to university psychiatric hospitals, an asylum such as Illenau in Achern (Baden), which opened its doors in 1842, under its inaugural director Christian FW Roller, was probably the intellectual center of German psychiatry; Roller tutored many clinicians who later became leaders of the field, including Richard von Krafft-Ebing (see below). In 1854, Jacques-Joseph Moreau (“de Tours”), after a visit to a number of German asylums, noted, “the great scientific movement” in German psychiatry. This was the beginning of a vast scientific take-off.

Scandinavia

In the history of psychiatry, the contributions of the Scandinavian lands have been largely neglected, partly for linguistic reasons, partly for cultural blinkeredness.

Denmark. New-style, reformed asylums arose early in the Nordic lands. Denmark had receptacles for the insane dating back centuries. The city of Copenhagen had traditionally confined the “lunatics” at a so-called plague house. Yet following the British bombardment in 1807, living conditions for these unfortunates became intolerable, and the city decided to place patients at a castle at Roskilde, not far distant from the town. The asylum, which began accepting patients in 1816, became known as St. Hans Hospital. But there were other Danish centers too. In the course of the century, neurosyphilis became a common reason for asylum admission. In 1857, Friedrich Esmarch and Peter Willers Jessen, at an asylum in the province of Schleswig (then belonging to Denmark), proposed in the *General Journal of Psychiatry* (*Allgemeine Zeitschrift für Psychiatrie*) that the mysterious fatal disease then called “progressive paralysis” seemed to be a late consequence of primary syphilis. A landmark in Danish psychiatry was the work of Copenhagen’s Carl Georg Lange, professor of pathology at the

University and considered Denmark's "first neurologist," on "periodic depressive conditions," considered by Lange to be a separate illness for which he recommended lithium therapy.

Norway. As elsewhere in Scandinavia, psychiatry in Norway rested heavily on the German tradition of biologic and genetic investigation. The first state psychiatric hospital in Norway, Gaustad Mental Hospital, in a town of that name near Christiana, was founded by Herman Major, the "first psychiatrist of Norway," in 1855. Important research came out of Gaustad, including superintendent Hans Evensen's landmark studies of schizophrenia (showing different outcomes). In 1934, Ivor Asbjörn Fölling, a biochemist at the Rikshospitalet in Oslo, the Norwegian national research hospital, discovered the metabolic cause of a disease called phenylketonuria (PKU), one of the so-called "inborn errors of metabolism" and a cause of mental retardation: It was a genetic inability to metabolize the amino acid L-phenylalanine, causing toxic amounts of phenylalanine to accumulate in the brain.

Sweden. Georg Engström founded the first reformed asylum at Vadstena in 1829; thus, as scholar Lennart Wetterberg put it, "drawing a line between barbarism and humanity in Swedish psychiatry." National mental health legislation in 1858 stipulated that an asylum must be led by a physician. The teaching of psychiatry in Swedish universities, among the earliest such teaching anywhere, began in Uppsala in 1741, with Carl von Linné, the great classifier, lecturing on medicine, including psychiatry. At the University of Stockholm, called the Karolinska Institute, Eric Godelius gave the inaugural lectures on medicine, which embraced psychiatry as well, beginning in 1811. At Karolinska, later a world-famous research institute as well as a university, Wilhelm Öhrström, the first professor of psychiatry and simultaneously head of the newly built Konradsberg psychiatric hospital, began lecturing in 1861.

Spain

Although an asylum was established at Valencia in 1409, the great clinical school of Spanish psychiatry that flourished in the Middle Ages had little continuity into the modern era. In the 19th century, Spanish psychiatry remained much under the influence of the French, and it was Madrid's Pedro Mata y Fontanet who established forensic psychiatry in Spain as the inaugural holder of the chair from 1843 when he helped introduce Esquirol's ideas. The overwhelming figure in modern Spanish neuroscience is Santiago Ramón y Cajal ("Ca-HAL"), who taught anatomy and pathology at the universities of Barcelona and Madrid. From 1888, Ramón established the neuron theory of brain histology and is generally acknowledged as the father of modern neuroscience (he received a Nobel Prize in 1906). His advice for a young investigator (1897, in Spanish) remains compelling reading for young scientists even today. Although he did not practice clinical psychiatry, many later prominent psychiatrists trained in the "Cajalian" phase of Spanish medicine (but note that he is generally referred to as Ramón, not Cajal, which was his mother's name). The main chairs of psychiatry were founded in the last years of the Second Republic (1931–1936), and the most important 20th-century clinical figure in Spanish psychiatry, Juan J. López Ibor, who originated the concept of "vital anxiety" (*timopatia ansiosa*), held the chair of legal medicine, toxicology, and psychiatry in Madrid from 1932.

United States

In 1751, the Society of Friends (the Quakers), assisted by Benjamin Franklin, founded in Philadelphia the Pennsylvania Hospital; it was the first institution in the United States to have a major psychiatric division, for "persons distempered in mind," opened by Benjamin Rush in 1793. Rush was one of the signers in 1776 of the Declaration of Independence and practiced as much general internal medicine as he did psychiatry in his years of service from 1783 to 1813. In 1812, Rush wrote the first American psychiatry textbook, *Medical Inquiries and Observations*, *upon Diseases of the Mind*—

and thus earned the sobriquet “father of psychological medicine in America.”

The first state hospital in the United States opened its doors in 1773 in Williamsburg, Virginia. Called “The Public Hospital for Persons of Insane and Disordered Minds,” it later became the Eastern State Hospital. Meanwhile, a series of private and charitable psychiatric hospitals sprang up on the model of the Pennsylvania Hospital. In 1817, the Quakers, alarmed at overcrowding in the Pennsylvania Hospital, founded a Retreat in nearby Frankford, Pennsylvania. In 1818, the psychiatric division of the Massachusetts General Hospital (incorporated in 1811) was founded at Charlestown in Boston and named (after a private donor) the McLean Hospital. The Retreat in Hartford, Connecticut, opened in 1824 and still exists today under the name Institute for Living (see below).

In 1771, a charter was granted to The Society of the New York Hospital, and in 1791, New York Hospital began accepting patients, including psychiatric; in 1808, it constructed a separate “lunatic asylum” for this purpose. At this point, the reforms of Pinel and Tuke had begun to arouse interest in the New World, and shortly proposals for “moral treatment” were circulating in New York as well. The trustees of New York Hospital, therefore, purchased a lot fronting the Bloomingdale Road in Harlem, and in 1821 the new structure named the Bloomingdale Asylum was opened, receiving private patients as well as those subsidized by funds from the Society of the New York Hospital. Years later, the Society decided that country air might be more salubrious, and in 1894 transferred the Bloomingdale patients to a new site in White Plains, Westchester, where it became the Westchester Division of The New York Hospital-Cornell Medical Center (see below for further developments).

The first large state hospital run on enlightened principles in the United States opened at Worcester, Massachusetts, in 1833, under the leadership of Samuel B. Woodward, an enlightened and forward-looking psychiatrist and close friend of Eli Todd at the Hartford Retreat. Following a lobbying campaign by Dorothea Dix, the hospital was enlarged in 1835, and on several subsequent occasions, this victory marked the beginning of Dix's career as an advocate on behalf of poor people with mental illness. Among the most influential of the early American state hospitals was the Utica Hospital, opened in 1843, part of the vast New York State system of hospitals, which served as a seedbed for successful hospital administrators in many other institutions.

The shift in U.S. psychiatry from large buildings with long corridors to small villas clustered in village-like colonies began in 1894 with the foundation of the Colony for Epileptics in Sonyea, New York ("Craig Colony" after Oscar Craig, president of the New York State Board of Charities); the first patient was admitted in 1896. With colony care, these mental hospitals adopted a more human face.

THE FIRST BIOLOGIC PSYCHIATRY

The intellectual content of this budding young discipline was overwhelmingly biologic. At the beginning, psychiatry had a profound physical orientation. The brain was seen as the seat of diseases of the mind, and treatments addressed the brain and the body as a whole. In 1672, Oxford physician Thomas Willis (who described the "circle of Willis") said of the brain's role in his famous *Two Discourses Concerning the Soul of Brutes*

> When it happens that these corporeal functions are defective or hindered, forthwith the eye of the intellect, as if covered with a veil, is wont to be very much dulled or wholly darkened . . . Because [of] their powers being hindered … the imbecility and dullness of the mind, the slowness of the ingenuity, stupidity and madness at length do often arise. The fault is either in the brain itself, or the animal spirits, or both together.

For many decades, investigations of the brain to ascertain the correctness of Willis's views were hindered by the lack of suitable stains for nervous tissue. Studies of inheritance became the main technique of biologic psychiatry. But in the 1870s, a new school of neuropathology, seconded with the aid of the microscope, began to arise, and the findings of such investigators as Theodor Meynert in Vienna and Franz Nissl in Heidelberg (see below) gave new impetus to biologic thinking.

Nerves

Intrinsic to biologic views was the assumption that disorders were caused by the nerves. Beneath the level of frank “insanity” or “madness,” depression, anxiety, obsessive-compulsive disorder, and other nonpsychotic complaints were thought nervous in nature. The view was that the nervous system was somehow physically affected and that the source of mental and behavioral symptoms lay in these ailing nerves. In 1780, Samuel Tissot of Geneva, whose practice included many patients with psychiatric disorders, said, “Among the most appropriate remedies for diminishing the irritation of the nerves, and to destroy numerous causes of their disorders, one must place the baths, cold or warm.”

By the mid-19th century, the concept of “nerves” had seized psychiatry in the way that “psychoneurosis” and “mood disorders” would later rule. English law distinguished clearly between insanity and nerves. As the asylum inspectors reported in 1844, “Homes which are licensed for the reception of Insane Persons ought to be kept exclusively for that purpose and the reception of nervous, imbecile, and dejected [depressed] persons, amongst those who are insane and often dangerous, is for obvious reasons open to serious objection.”

Psychiatrists were once called “nerve doctors,” a term that persisted in German-speaking Europe until relatively recently (Nervenarzt); a “nervous breakdown” crossed the threshold into psychosis, rendering patients incapacitated in a way that is associated with melancholic illness, acute psychosis, and delirious mania. In 1851, Henry Monro, an attending at St. Luke’s Hospital in London, said in his Remarks on Insanity, “The symptoms of insanity are simply the consequence of loss of nervous power.” He called insanity “simply a disease of deficient nervous vigour.” These words hallmarked a century of biologic psychiatry.

Predisposition, Degeneration

Psychiatrists have always believed that many mental illnesses can be passed on from generation to generation, that they are “inheritable,” or the result of “predisposition.” The psychoanalysts did not believe this and attributed reproducibility within families to “nurture” rather than “nature.” Yet, in the great sweep of things, psychiatry as a whole has believed in nature. As London’s John Haslam said in 1817, “The minute investigation of many hundred cases has fully satisfied my own mind that the offspring of a person who has labored under insanity, is peculiarly liable to become similarly affected.” By the late 19th century, it had become an accepted fact that the main cause of psychiatric disease was “heredity.” As Paris psychiatrist Ernest Billod toured Italian asylums in the early 1880s, he was struck at the mantra-like repetition of the phrase, “The predominant cause of mental illness is heredity.”

Early Pharmacotherapy

In psychiatry’s early period of biologic thinking, before the rise of psychotherapy, treatments of mental disease borrowed heavily from the “humoral” remedies employed elsewhere in medicine, mainly the therapies of “depletion”: Correcting humoral imbalances in the body by venesection (on which Philadelphia’s William Rush was very keen), leeching, and the administration of purgatives and laxatives. At the same time that depletion began to totter in the rest of medicine—toward the mid-19th century—it came under attack in psychiatry as well and was replaced by the whole world of physical and dietetic therapies. All such treatments rely mainly upon the placebo effect, but at least they are not, unlike depletion, actively harmful to the patient. As Woodward wrote in 1850,

> The abandonment of depletion, external irritants [mustard plasters], drastic purges and starvation, and the substitution of baths, narcotics, tonics and generous diet, is not less to be appreciated in the improved condition of the insane, than the change from manacles, chains, by-locks and confining chairs, to the present system of kindness, confidence, social intercourse, labor, religious teaching, and freedom from restraint. In this age of improvement, no class of mankind have felt its influence more favorably than the insane. (Woodward SB. Observations on the medical treatment of insanity. *Am J Psychiatry*. 1850;7(1):1–34.)

There was in the mid-19th century a brief but lucid anticipation of the era of psychopharmacology that would follow a hundred years later: In 1845, Paris psychiatrist Jacques-Joseph Moreau (nicknamed “Moreau de Tours,” after the medical school he attended) published the results of his therapeutic experiments with hashish. The essence of psychopharmacology is establishing differential effectiveness, and in this foundational work, Moreau established that hashish was ineffective in the treatment of dementia and stupor (*stupidité*), but that it did seem to have antimelancholic effects, lifting the mood and abolishing psychotic ideation in two melancholic patients.

As for subsequent pharmacotherapies, the opinion is widely held that psychiatry possessed no pharmacologic treatments before the psychopharmacologic revolution of the 1950s (see below). This is false. Psychiatry has always disposed of a palette of agents, admittedly of varying effectiveness (yet that is true today, as well). Until the Second World War, the Germans led the pack. In the area of medicinal innovation, in the years 1800 to 1930, Germany had 44% of the world’s total innovations, followed by France at 16% and the United States at 14. The German chemical industry began its take-off around 1860, dyes in the forefront, and from the dyes emerged the first generation of psychopharmaceuticals. The very first treatments, however, were as old as the hills.

Ethanol. People are accustomed to thinking of beverage alcohol as a source of substance abuse rather than a useful therapeutic agent. Yet before the Second World War, although the dangers of alcoholism were readily acknowledged, alcohol constituted an important treatment. In 1923, Alexander Westphal, director of the university psychiatric hospital in Bonn, said, “In milder cases of melancholia, alcohol as a sedative and hypnotic can yield good service.” The opinion was typical of the psychiatry of the day and not necessarily incorrect.

Opium. The milky juice of the unripe poppy plant *Papaver somniferum* in the treatment of melancholia goes back to the

Ancients and was revived in the 17th century by London physician Thomas Sydenham, who standardized a combination of opium and alcohol (sherry) in “laudanum,” or opium tincture. Practitioners of mental medicine began prescribing opium in the 18th century, and in 1788, William Falconer was found, in his discourse upon “the influence of the passions,” waxing enthusiastic: “Opium too, which has been introduced into practice of late years in the nervous fever, and frequently administered, and in pretty large doses, is well known to exert great cordial effects on the mind and spirits.” Tincture of opium does not seem to have been highly addictive because so much of the alkaloid is inactivated by stomach acids. But with the invention of the syringe in the 1850s, it became possible to inject opium, and the resulting epidemic of addiction caused many psychiatrists to back away from the poppy, which seems actually to be quite effective as an antimelancholic. Yet as late as the 1960s, Hoffmann-La Roche Laboratories marketed injectable opium (Pantopon) for indications including psychiatric.

Cannabis and Hashish. The derivatives of *Cannabis sativa* L have a long history of use—today quite forgotten—in psychiatric therapeutics. After Moreau’s work in 1845, hashish became widely prescribed. Auguste Voisin, the professor of psychiatry at the Salpêtrière in Paris, described hashish in 1883 as part of the panoply of agents, including potassium bromide and hydrotherapy which he deployed in the treatment of psychotic depression. Cannabis has a similar history of age-old use and was marketed as a drug in England in the 1930s under the brand name Indonad (in Germany as Indonal-Bürger). The cannabinoids became definitively stigmatized in the “war on drugs” of the 1970s and disappeared from psychological medicine.

Lithium. Lithium had drifted on and off the therapeutic palette for decades, if not centuries. Certain mineral springs in Texas containing lithium, for example, had a historic reputation as “crazy water.” In 1886, Copenhagen psychiatrist Carl Georg Lange proposed lithium in the treatment of melancholic depression. But the remedy did not catch on, as the concept behind it, a uric acid diathesis of mental illness, was soon abandoned. (On the later history of lithium, see below.)

Sedatives and Hypnotics

Medicine's encounter with sedatives goes back to 1857 when the salts of bromine ("bromides") were introduced. Among chemically synthesized sedatives, chloral hydrate followed in 1869 (and is still in use today). Paraldehyde was introduced in 1882, and a number of other synthetic sedatives were launched—all now long forgotten. The barbiturates, however, were one of the major drug classes of the 20th century. A mixture of uric acid and malonic acid, the first barbiturate, barbital sodium (Veronal), was marketed in 1903, phenobarbital (Luminal) in 1911, and then dozens of shorter half-life preparations, including amobarbital (Sodium Amytal) in 1924 and butabarbital (Butisol) patented in 1932. These agents became household names and were widely prescribed.

Despite this proliferation of agents for mild depression and anxiety, psychiatry lacked treatments for such major illnesses as schizophrenia, melancholic depression (with the exception of opium), and catatonia. In 1892, Daniel Cathell, a Baltimore physician whose practice was heavy with nervous patients, advised his colleagues,

> Should you ever have recourse to remedies intended to act chiefly through the mind, look your patient earnestly in the face … they will do double good.…You will not only find that almost anything will relieve some of these cases, but will be further surprised to learn that it has evoked great mental and spiritual enthusiasm, and that they are chanting its praise and vowing that they were cured of one or another awful thing by it.…Some, indeed, who seem to be magically benefited by doses of—nothing—will actually credit them with saving their lives. (Cathell DW. *Book on the Physician Himself: And the Things That Concern His Reputation and Success*, The Twentieth Century Edition. F.A. Davis; 1903:190.)

The jury is still out on whether this happens today. (This thread is continued below under "The Psychopharmacologic Revolution.")

PSYCHOTHERAPY, SOCIAL PSYCHIATRY

Early Psychotherapy

Although physicians have always practiced an informal kind of psychotherapy in the doctor–patient relationship itself, formal psychotherapy begins with Hippolyte Bernheim, professor of medicine at the University of Nancy in eastern France, in 1884, when Bernheim, in his book *On Suggestive Therapy under Hypnosis or in the Waking State* (*De la Suggestion dans l'État Hypnotique et dans l'État de Veille*) distinguished between hypnotic suggestion (which had been around for a century) and nonhypnotic suggestion, or a good talking-to. In 1904, Paul Dubois, professor of neuropathology in Berne, Switzerland, proposed "rational psychotherapy," a forerunner of today's cognitive-behavioral therapy (CBT), in his book The Psychoneuroses and Their Psychological Treatment (*Les Psychonévroses et leur Traitement Moral*). In 1903, Pierre Janet, professor of experimental psychology at the Sorbonne, proposed "psychasthenia" as the main mental disorder and advocated a kind of cathartic therapy for its treatment. These early systems were then overwhelmed by psychoanalysis, which by the 1920s had become the chief psychotherapy of psychiatry (see below), and were forgotten.

Psychoanalysis

Previous histories of psychiatry customarily gave great space to the history of psychoanalysis, or Freudian "depth psychiatry." Yet today, psychoanalysis has virtually disappeared from psychiatry, and such extended coverage seems pointless. For detailed accounts, the reader is referred to the author's own *History of Psychiatry* (1997) or to one of the frankly adulatory chronicles of Freud's life such as that by Peter Gay. In retrospect, psychoanalysis may be seen as a kind of hiatus in an ongoing current of biologic thinking in psychiatry that began with the old asylum physicians around the middle of the 19th century and revived with enthusiasm about drug treatments in the 1950s, resulting in the substantial displacement of psychoanalysis by psychopharmacology, neuroimaging, molecular genetics, and other forms of neuroscientific investigation in the 1970s. The following discussion is appropriately brief.

Psychoanalysis, a system of thought that attributes the origin of behavioral symptoms to conflicts within the unconscious mind, was originated by Vienna's Sigmund Freud in the late 19th century. Although *Studies in Hysteria*, the volume that Freud coauthored with Vienna family physician Josef Breuer in 1895, is commonly seen as the founding document of psychoanalysis, it merely presents psychiatry's most famous patient, "Anna O" (Bertha Pappenheim), in the context of abreactive therapies. Freud's seminal doctrines themselves come to blossom only in 1900 in The Interpretation of Dreams (*Die Traumdeutung*). In successive years, Freud slowly adumbrated the essentials of psychoanalytic treatment, explaining the role of the interpretation of dreams and of free association. Then in the early 1920s, Freud proceeded to trace the architecture of the psyche in the layers that he hypothesized: ego (conscious mind), superego (the source of morality, supposedly derived from oedipal fears toward the father), and the id (unconscious mind, harboring the sex drive and the death instinct).

Psychoanalysis as a movement began in 1902 when Freud founded a discussion group called the Psychological Wednesday Society, a group of curious physicians—many of them spa physicians and physiatrists in search of some kind of psychic bond to their patients. In 1908, this discussion group became the Vienna Psychoanalytic Society. In the same year, the first international congress of psychoanalysis took place in Salzburg, followed by a second congress in 1910 in Nuremberg, and a third in 1911, in Weimar. Meanwhile, the movement was plagued by schisms as early advocates such as Alfred Adler broke away, unable to accept Freud's doctrine of infant sexuality fully.

After the First World War, psychoanalysis became a major international movement. The dominant form of medical psychotherapy shifted from the former systems of Dubois and Janet to psychoanalysis. Psychoanalytic societies sprang up in the major western cities, and only with the Nazi seizure of power in 1933 (and Anschluss with Austria in 1938) was this expansion brutally braked.

As the movement leached out of Europe, the United States, especially New York, Washington DC, and Los Angeles, became the world epicenter of psychoanalysis.

In the New World, under the influence of such émigé analysts as Hungarian-born Sandor Rado in New York, depressive neurosis began to loom in psychoanalysis. Freud himself had little interest in depression because the patients wanted mainly to be left alone and not tell their dreams or free associate. But in New York, “depressive neurosis,” or “neurotic depression,” started to become the meat-and-drink of the Park Avenue analysts, as opposed to “hysteria,” “phobic neurosis,” and the other diagnoses that Freud himself had placed front and center. In 1931, at the request of Abraham Brill, Rado helped organize training at the newly founded New York Psychoanalytic Institute. After a disagreement with other members, in 1945, Rado headed the newly opened Columbia University Psychoanalytic and Psychosomatic Clinic for Training and Research, the first training institute within a university.

Once psychoanalysis had drifted into exile, the movement began to break into rival camps, such as ego psychology (the classic drive-defense tradition as continued in Anna Freud’s 1936, *The Ego and the Mechanisms of Defense*); Donald Winnicott and Melanie Klein’s object relations theory; and self-psychology (associated in particular with Heinz Kohut’s book *The Analysis of Self* [1971]).

In object relations, Melanie Klein’s *The Psycho-Analysis of Children* (1932) highlights the importance of introjection and projection as mechanisms. As Klein’s biographer John Arnold Lindon explained, “Projection alters the infant’s impression of his environment, and by introjection this changed picture of his environment influences what goes on in his mind. Thus an inner world is built up that is partly a reflection of the external one.”

After the 1970s, psychoanalysis became less quarrelsome and drifted even further from Freud’s original emphasis on infantile sexuality. Psychodynamic psychiatry (which is not the same thing as psychodynamic psychotherapy) agrees on the importance of unconscious conflict, psychic determinism, the role of development, transference, counter-transference, and resistance. The field is no longer opposed to medication (analysts once scorned “pills” as a hindrance to getting at the “root causes” of the complaint). Glen Gabbard at Baylor College of Medicine in Houston writes in 2009,

> A patient with a bipolar disorder who is denying that he has an illness and refusing to take lithium may ultimately have better compliance with the medication if the clinician explores the meaning of his denial and his reluctance to consider himself as someone requiring treatment.

Yet, despite the efforts of psychoanalysts to integrate findings from psychopharmacology and the neurosciences, the wind has slowly gone out of the field. There had been a time when the chair of virtually every major department of psychiatry in the United States had been a psychoanalyst. But by 1990, more than 100 of 163 residency programs for psychiatry had abandoned instruction in intensive psychotherapy. The percent of psychiatrists who were also psychoanalysts declined from around 10% in the 1950s to 2.7% by 1988. What once was the very intellectual core of the discipline of psychiatry has become a marginalized group of enthusiasts. As Arthur Yuwiler, a senior biochemist in the Department of Psychiatry at the University of California, Los Angeles (UCLA), reflected somewhat ruefully in 2004, on the exchange of the psychoanalytic paradigm for the biologic one, “I seemed to spend the first half of my scientific life arguing with psychiatrists that there was a brain as well as a mind and the last half arguing there is a mind as well as a brain.”

Nonpsychoanalytic Psychotherapies

Formal systems of psychotherapy began with Hippolyte Bernheim, an internist in the French provincial medical school at Nancy, in 1884, with his distinction between hypnotic and nonhypnotic “suggestive” therapies: the latter meant, essentially a good chat. Bernheim believed hypnosis to be an effective treatment. Jean-Martin Charcot, in Paris, however, thought hypnotizability to be merely a diagnostic marker of “hysteria.”

Group psychotherapy began with Scottish psychiatrist William Alexander Francis Browne at the Crichton Royal Hospital in

Dumfries in 1842 when he encouraged patients to stage amateur theatricals that amounted to a form of “mental therapeutics.” This strand was continued in 1922 in Vienna with Jakob Moreno-Lewy’s impromptu theater that was later tagged “psychodrama.” After Moreno immigrated to the United States in 1925, he introduced in 1931 group psychotherapy. Independent of Moreno, in these years, Louis Wender at Hillside Hospital and Paul Schilder at Bellevue Hospital, both institutions in New York, also began psychotherapy in groups. Closely related to group psychotherapy was the “therapeutic community,” which was birthed in England during the Second World War at the hands of Joshua Bierer and Thomas Main. (See section on social psychiatry.)

In the United States, the transition of psychotherapy from physicians to psychologists and psychiatric social workers began with psychologist Carl Rogers’ “client-centered therapy” after 1946. His book of that title appeared in 1951.

Family therapy is generally considered to have begun with Columbia University’s Nathan Ackerman at the founding in 1956 of the “family mental health clinic,” part of New York’s Jewish Family Service.

Social and Community Psychiatry

The main narrative arc in psychiatry is basically a first (19th-century) biologic psychiatry, then a psychoanalytic hiatus in the first half of the 20th century, followed by a second biologic psychiatry (late 20th century). Yet in the years 1940 to circa 1980, another current arose in psychiatry flowing separately from this main narrative stream: it was social and community psychiatry.

After the Second World War, the field became increasingly preoccupied with the social causation of illness and with group therapies for its treatment. A movement arose to treat patients in the context of the community rather than the asylum, and in 1946, D. Ewen Cameron, head of psychiatry at McGill University, created the first day hospital in the world at the Allan Memorial Institute in Montreal. In 1948, Joshua Bierer established the first in England, a "social club" at the Social Psychiatry Centre in London that he had founded two years previously. The movement incorporated, in 1959, Bierer's view that "Treatment must include the whole social environment of the patient and all his social relationships. He must be treated not only as a person but as part of a community." So influential did social psychiatry become in the United States that it influenced the removal of the National Institute of Mental Health (NIMH) in the years 1967 to 1992 from the National Institutes of Health, to protect, according to Joel Paris, head of psychiatry at McGill and author of *Fall of an Icon* (2005), "the social mission of the Institute from mainstream medicine." Many social psychiatrists also saw themselves as social reformers, on the grounds, as Paris continued, that "poverty and social disruption were the real causes of psychological symptoms." Therefore, "society, not the individual, should be the 'patient.'"

These ideas accorded well with the social activism of the mid-20th century. But as early as 1956, Ralph Gerard, a neuroscience leader at the University of Michigan, said presciently,

> We have all wished mental disease to be determined by sociological causes, because this situation seemed more hopeful from the therapeutic standpoint. The individual broken by the group could be healed by techniques of interpersonal interaction; but if he had bad genes, effective treatment was far in the future.

And indeed, in the United States, social psychiatry was rapidly eclipsed by mushrooming biologic perspectives.

Today, CBT is probably the most widespread form of medical psychotherapy and is associated with Philadelphia psychiatrist Aaron Beck from 1963. Popular as well is Interpersonal Psychotherapy, originated in 1967 by Yale psychiatrist Gerald Klerman and coworkers, especially for the treatment of depression. Also of interest is "dialectical behavior therapy" (DBT), a form of CBT emphasizing "mindful awareness," proposed by Marsha M. Linehan, a psychologist at the University of Washington, in 1999.

Yet while the number of psychotherapies proliferated, the percentage of psychiatric consultations in the United States that involved psychotherapy declined from 44.4% in 1996 to 1997 to

28.9% in 2004 to 2005. Clearly, the single-office psychiatrist with a primarily psychotherapeutic practice, once the very image of psychiatry with its emphasis on “the couch” and “root causes,” was giving way to the health care team with the psychiatrist’s primary purpose being diagnosis and the provision of medication.

FROM ASYLUM TO UNIVERSITY

In the last quarter of the 19th century, many national medical bodies began demanding that psychiatry be included in the medical curriculum. This created a demand for professors of psychiatry and for academic centers in which to train them. As a result of this curricular development, research began shifting from asylums to university psychiatric hospitals and academic departments of psychiatry. Investigators in many of these centers came to dominate the field, and the asylums became research backwaters, increasingly given over to warehousing the ever-growing numbers of patients rather than treating them.

German-Speaking Europe

Said British psychiatrist Malcolm Lader in 1990, “We always used to say if you go back far enough and look at German literature at the turn of the century, you’re sure to find that someone described panic disorder and everything else.” It was the closeness of the link between the academy and the psychiatric hospital that granted this extraordinary German celerity in psychopathology; much of this architecture of the delineation of syndromes still remains. This leap from asylum to the academy in German-speaking Europe sped forward in 1874 when for the first time, university professors began taking part in the Association of Southwest German Alienists, hitherto a group of influential asylum psychiatrists.

Vienna. The capital of the Austro-Hungarian Empire, Vienna was a psychiatric super-power, the global influence of which was far disproportionate to the medium size of the city. The train of distinguished psychiatrists began in the late 18th century with such figures as Franz Joseph Gall (who first speculated about cerebral localization) and continued into the 19th with Ernst von Feuchtersleben, whose 1845 Textbook of Medical Psychiatry (*Lehrbuch der ärztlichen Seelenkunde*) popularized the term "psychopathy," in the sense of a disordered personality. (Feuchtersleben also distinguished between "neurosis" and "psychosis," giving them exactly the opposite meaning they were later to have.) But the modern tradition of Vienna as a bastion of biologic psychiatry (psychoanalysis came later) began with psychiatry professor Theodor Meynert ("MY-nert") with his great 1869 treatise on neuroanatomy, *The Architecture of the Cerebral Cortex (Der Bau der Gross-Hirnrinde)*, and continued with *Illnesses Involving the Forebrain in 1884 (Erkrankungen des Vorderhirns)*, which was completely forgotten midst later shrieks of jubilation about the importance of the frontal and prefrontal lobes in schizophrenia. His successor Richard von Krafft-Ebing is remembered for his textbook of sexology Psychopathia Sexualis (1886); his successor, in turn, Julius Wagner von Jauregg ("YOW-reg"), introduced in 1917, the malarial fever cure, an epochal accomplishment for which he received the Nobel Prize in 1927. Aside from the professors, Josef Berze, head of the Vienna city asylum "Am Steinhof," described "primary insufficiency of psychic activity" in schizophrenia in 1914, and Constantin von Economo, who led a brain research institute, reported the new disease of "encephalitis lethargica" in 1917. It was in the years following 1930 that Manfred Sakel proposed insulin coma therapy (while still in Berlin; only in 1933 did Sakel return to Vienna to conduct clinical trials—see below). Finally, pediatrician Hans Asperger described "autistic psychopathy" in 1944, among the earliest descriptions of autism (which was first used as a term in pediatric psychiatry by German and Russian neurologists and psychiatrists early in the 1920s). Vienna's contribution to psychoanalysis would begin in 1900, with the publication of Sigmund Freud's *Interpretation of Dreams* (see above), and continue until the expulsion or murder of the Jewish psychoanalysts in 1938 after Anschluss with Germany. After the Second World War, Vienna never again regained this historic preeminence in psychiatry.

Heidelberg. The flagship of academic psychiatry in the German Empire berthed in Heidelberg. The “Psychiatric-Neurological Clinic” of the University (“Klinik” in German means university hospital) was founded in 1879 by Otto Fürstner; it was the first university psychiatric department with beds of its own so that patients didn’t have to be brought from a nearby asylum for demonstration in clinical lectures. Its most distinguished head was Emil Kraepelin, who had the professorship from 1891 to 1903, during which time the crucial editions of his textbook appeared (see below). The Klinik was also a provincial asylum with a catchment basin of its own. When Kraepelin left for Munich, the professorship was assumed by neuropathologist Franz Nissl, known for his demonstration in cells of the “Nissl substance.” At various points, Kraepelin’s Klinik served Alois Alzheimer (who followed Kraepelin to Munich) and Karl Jaspers. In the 1920s, such important figures as Willi Mayer-Gross (who after fleeing the Nazis to England coauthored the standard English psychiatry textbook, *Clinical Psychiatry*, in 1954); Carl Wilmanns (pioneering studies of the homeless); Hans Gruhle (premier schizophrenia researcher of his day); and August Homburger (who founded in Germany modern pediatric psychiatry). This wall of scholarship crumbled in 1933, and the names of the successors under the Nazis are either forgotten or live on in infamy. Heinz Lehmann later said in retrospect, “German medicine was an impressive thing and there is no doubt about it. When we all went away, I don’t think this tradition was transferred to America but it was abolished in Germany.”

Berlin. In 1795, a psychiatry department was founded in the Charité, the Prussian state’s great military hospital, and in 1806 Ernst Horn was called to become associate director of the hospital, with simultaneous responsibility for psychiatry. Under Horn, psychiatry at the Charité conformed to the concepts of the day of a proper reformed asylum, though Horn was much assailed for some of his practices and left under a cloud in 1818. Ten years later, he was succeeded by Carl W. Ideler, one of the so-called “Romantic” psychiatrists who saw illness as evidence of sin. This unhappy period came to an end with Ideler's death in 1860 and Wilhelm Griesinger's arrival in 1865 to convert the old psychiatric ward into a modern neuropsychiatric clinic (Klinik für Geistes- und Nervenkrankheiten). In 1867, Griesinger founded the lead German journal for biologic psychiatry, the *Archive for Psychiatric and Neurological Diseases* (*Archiv für Psychiatrie und Nervenkrankheiten*, of which the current *Archives of General Psychiatry*—now called *JAMA Psychiatry* is a distant echo). Griesinger died prematurely in 1868 of acute appendicitis. Following Griesinger came a distinguished series of biologically oriented psychiatrists, including Carl-Friedrich Westphal in 1869 (who in 1872 described agoraphobia and in 1877 obsessive-compulsive disorder). His tenure ended with his death in 1890 of what seems to have been neurosyphilis—of which so many middle-class men perished in those days (infected as medical students or law students with primary syphilis from prostitutes). Karl Bonhoeffer had the Berlin chair from 1912 to his emeriting in 1937, after which another grim period began in the history of German psychiatry. In 1909, Bonhoeffer conceived the notion of "exogenous psychosis," arising from stress or toxins from outside rather than being endogenous and inborn.

In a separate development, in 1902, Oskar Vogt founded a neurobiologic institute at the University, which in 1915 was joined with the Kaiser-Wilhelm-Institute for Brain Research. (His wife, the French-born Cécile Vogt, became an important neuroscientist, later settling in England. Their daughter Marthe discovered in 1965 that noradrenalin was present in the brain.) In 1931, the institute was transferred to the Berlin-Buch mental hospital and came in 1937, under the direction of Hugo Spatz, who was a member of the Nazi party but who goes down in history as co-discoverer of the Hallervorden–Spatz disease of neurodegeneration. Despite its vicarious history, this institute became one of the world's leading neuroscience centers.

Munich. When in 1903, Kraepelin went from Berlin to Munich, it was as the inaugural director of a newly built University Psychiatric Hospital in the Nussbaumstrasse. He proceeded to make it into a world-class institution, bringing, as stated, Alois Alzheimer from Heidelberg to head the pathology laboratory, to which young investigators streamed from all over the world.

In 1917, Kraepelin founded a freestanding psychiatric research institute, the Kaiser-Wilhelm-Institut für Psychiatrie. The psychiatric department of the adjacent Schwabing City-Hospital, headed after 1931 by Kurt Schneider, became its clinical arm. Slow to get off the ground, the Institute’s take-off began only in the mid-1920s, thanks to a group of foreign donors led by James Loeb (after whom a street in front of the present institute is now named). In 1917, Ernst Rüdin became head of the “genealogic-demographic” (genetics) section (see below). The scientific promise of the Institute was nipped in the bud by the Nazi takeover, and only after the war, when in 1954 it became the Max Planck Institut für Psychiatrie, did its international reputation blossom.

Zurich. In Zurich, a city psychiatric hospital was founded in 1860, and when Wilhelm Griesinger began lecturing there in 1863, it became a “Klinik.” Two years later, in 1865, Griesinger decamped for Berlin. In 1869, a grand new Klinik was planned at a spot called the “Burghölzli”; the “Bli,” as it was known, was helmed over the years by some important figures, including Auguste Forel (1898–1927), a co-originator of the “neuron theory” of cerebral communication; Eugen Bleuler (1898–1927), who coined the term “schizophrenia”; and his son Manfred Bleuler (1942–1969), who in 1954, determined that the prognosis of schizophrenia was often benign.

France

Paris is the great focus of French psychiatry, and in Paris, each of the main general hospitals had academic psychiatry departments chaired by professors. Yet in addition, Paris had one special institution not found elsewhere in France (or in other lands, for that matter): The special psychiatric reception service of the Prefecture of Police (la Infirmérie Spéciale des Aliénés de la Préfecture de Police).

In 1800, Paris was given a special prefect for police, and with the general mental patients law of 1838, this prefect acquired responsibility for mental patients who came to public attention. Seven years later, in 1845, this special reception service became headed by a psychiatrist. From this service flowed a good deal of the research of modern French psychiatry. The first head of note was Ernest-Charles Lasègue in 1850, who coined the diagnostic term “delusions of persecution” in 1852, and “hysterical anorexia” (anorexia nervosa) in 1873. (Lasègue also had a series of academic appointments in the teaching hospitals.) In 1872, the Infirmérie Spéciale became independent of the police headquarters and turned into an important center for research. Following his death in 1883, Lasègue was succeeded by his assistant Henri Legrand du Saulle, who in 1875 offered an early description of obsessive-compulsive disorder (*la folie du doute avec délire du toucher*).

At the Salpêtrière hospice in 1882, Jean-Martin Charcot became the inaugural holder of a chair in nervous diseases, created especially for him by the president of the Republic. Charcot’s contributions lay mainly in neurology, but his name is indissolubly connected with a certain kind of “hysteria,” involving supposed chronic stigmata and elaborate acute pantomimes that in retrospect were phenomena of suggestion and that disappeared after his death in 1893. Among the students of Charcot, best known is Joseph Babinski, who in 1896 described the plantar extension reflex that is named after him. Charcot’s successors Fulgence Raymond and Jules-Joseph Dejerine were better known as neurologists than psychiatrists.

The “clinical asylum” Sainte-Anne was opened in 1867 as the asylum of the Seine department, with Valentin Magnan, the notable advocate of “degeneration” theories, as director of its admissions department. In 1877, Benjamin Ball became the inaugural holder of the Chair of Mental and Brain Disease. Among his successors were Henri Claude in 1922, an early biologic psychiatrist, and Jean Delay in 1946, who introduced the psychopharmacological era in France. The facility became a “psychiatric hospital” in 1937, a “psychiatric center” in 1944, and a “hospital center” (shedding the unfashionable adjective “psychiatric” entirely) in 1974.

United Kingdom

London. In 1908, the asylums committee of the London County Council accepted a gift from psychiatrist Henry Maudsley to found a research hospital based on the model of the German university psychiatric clinic. The war interfered with the realization of these plans, but in 1923, the Maudsley Hospital opened its doors for psychiatry with Edward Mapother, its inaugural superintendent. The Maudsley was not to be an asylum. Mapother made clear, as historian Edgar Jones relates (in a 2003 article in Medical History), “that no patient was to be admitted under section, nor would they be certified once in the hospital.” Mapother had an academic appointment at King’s College Hospital and wanted to make the Maudsley the psychiatric arm of the college’s teaching. (Mapother received the title “professor” in 1936.) Aubrey Lewis, who joined the staff in 1928, becoming a medical officer in 1936, recalled, “The place was small, full of ambition and energy, but everybody was overworked.” In 1946, Lewis was appointed professor of psychiatry, and two years later, in 1948, the teaching unit at the Maudsley was renamed Institute of Psychiatry (IOP). In that year as well the Maudsley merged with the Bethlem Royal Hospital (the former “Bedlam”). Lewis began adding Medical Research Council (MRC) units; the first of these, the MRC Social Psychiatry Unit under Lewis himself opening in 1948. These helped make the Maudsley the premier institution in the United Kingdom for research in psychiatry. In 1997, the IOP split from the Maudsley to become a school of King’s College London. The Maudsley was a major font of social psychiatry in the United Kingdom. Psychiatrist David Healy recalled that Aubrey Lewis had stated, at a meeting in 1958 (in Healy’s words), “‘If we had a choice between the new drugs and the social treatments, such as industrial rehabilitation units, we would pick social treatments.’ And it’s interesting that in the UK under Lewis’ influence, the Maudsley remained very aloof from the new drugs.”

Accordingly, the first center of research for psychopharmacology in the United Kingdom—the first anywhere—was the Department of Experimental Psychiatry, founded by Joel Elkes at Birmingham in 1951. It was here that some of the earliest trials of the antipsychotic chlorpromazine were conducted. “I felt like a naturalist advancing into a strange continent,” said Elkes later. The notion that drugs, as opposed to psychotherapy, could prove curative in psychiatry was then very new.

On Scotland and Ireland (See in Early Beginnings Section)

Canada—McGill University

Canada contained one of the most internationally important departments of psychiatry at McGill University in Montreal. The Department of Psychiatry of McGill was the Allan Memorial Institute (named after a donor), founded in 1940 at the instigation of neurosurgeon Wilder Penfield. Chaired by D. Ewen Cameron from 1943 to 1964, it was under Cameron that the “Allan” became one of the most distinguished psychiatry departments in North America. Its clinicians and scientists included psychoanalyst Miguel Prados, who arrived from Spain in 1944; the neuropathologist Karl Stern who in 1944, established a gerontologic unit, the first in the world; the neuropathologist Vojtech Adalbert Kral, a Holocaust refugee who arrived at the Allan in 1953 and pioneered research in dementia; Clifford Scott, who became an international leader of psychoanalysis, arrived from the Maudsley in 1954. (One wag said, “Kral felt if you couldn’t see it, it didn’t exist and Clifford Scott … felt if you could say it, it wasn’t important.”)

Included as well were: Neurophysiologist Robert Cleghorn in 1946, who pioneered endocrinologic psychiatry; Charles Shagass in 1950, who conceived the notion of the “sedation threshold”; Eric Wittkower, who in 1955 set up the section on transcultural psychiatry as a joint venture with the department of anthropology; Wittkower recruited Henry BM Murphy, author of the standard textbook of transcultural psychiatry (Comparative Psychiatry, 1982), who became head of the section in 1965 after Wittkower retired; and Heinz Lehmann, who came to Montreal in 1947 as director of the Verdun Protestant Hospital and is considered one of the founders of psychopharmacology. (The World Health Organization's first training center for psychopharmacology was at the Douglas.) Psychiatrist George Simpson, a first-year resident at McGill in 1956, later said in an interview, "I would argue that the Allan was the most stimulating place in the English-speaking world at that moment, even though the rest of the city spoke French."

United States

After the Second World War, the United States came to dominate world psychiatry, partly as a function of the torrent of research funds from NIMH, partly as a result of the Diagnostic and Statistical Manual of the American Psychiatric Association becoming after 1980, the world bible of psychiatry. The Holocaust and the devastation of the Second World War also had a great deal to do with the new American primacy. Rather than flocking to the Maudsley or Vienna for training, as budding American psychiatrists did before the war, it was young psychiatrists from all over the globe who sought further training in the United States. This new American hegemony accounts for the length of the following section.

New York. New York held the greatest concentration of psychiatric firepower in the United States owing to a series of public and private teaching hospitals.

HILLSIDE HOSPITAL. Hillside Hospital, initially in Hastings-on-Hudson, was founded by Israel Strauss in 1927 as a charitable Jewish hospital operated in a nonsectarian manner. In 1941, the hospital removed to Glen Oaks, Queens. It was, as Strauss put it, "the first institution of its kind for Jews in this country." Hillside specialized in "borderline" cases, meaning the kind of psychoneurosis that usually would not receive in-patient treatment. In 1930, Louis Wender, chief physician, began one of the first programs of group psychotherapy in the country. In the 1940s, Hillside was among the earliest U.S.

institutions to offer the various shock therapies. Although mainly psychoanalytic in inspiration, in 1950, Hillside resolved upon a “biochemical” research program, and in 1952 hired Max Fink to establish the Department of Experimental Psychiatry, which was joined by Donald Klein in 1957. Fink and colleagues set up an electroencephalogram (EEG) laboratory in 1953, and with Klein, conducted pioneering trials in psychopharmacology. By 1999, following several mergers, what had become Zucker Hillside Hospital was merged into the North Shore Long Island Jewish Health System, which encompassed seventeen hospital systems.

NEW YORK/PRESBYTERIAN/WESTCHESTER DIVISION. The foundation and growth of the New York Hospital, the second oldest freestanding psychiatric hospital in the United States, is discussed above. In 1898, the hospital became associated with Weill Cornell Medical College as that institution was founded, and a 1927 endowment lent to the psychiatric division the title Payne Whitney Psychiatric Clinic. New York Hospital merged with Presbyterian Hospital in 1996, and the Payne-Whitney Clinic was renamed the New York/Presbyterian Westchester Division.

NEW YORK STATE PSYCHIATRIC INSTITUTE. In 1896, the New York State Pathological Institute was established in New York City under Ira Van Gieson. It was the first effort in the state to study the anatomical basis of insanity, receiving specimens from the various state hospitals. In 1904, the Swiss-born Adolf Meyer, previously a pathologist at several state hospitals and a professor at Clark University, succeeded him. Meyer was already a significant scientific figure and would go on in 1910 to become a professor of psychiatry at Johns Hopkins University and inaugural head of the Henry Phipps Psychiatric Clinic (see below). In 1902, the Pathological Institute moved to Ward’s Island next to the Manhattan State Hospital. Meyer changed the name to Psychiatric Institute in 1907. Following a fire at Manhattan State, planning began to convert the institute to a state mental health research hospital and to situate it at Washington Heights, where Columbia was building a new medical school, and

Presbyterian Hospital was to move. The new building of the now New York State Psychiatric Institute was dedicated in December 1929. Known as “PI,” it became the psychiatry department of Columbia University as well offering from 1931 a 10-week course for psychiatrists in the New York State Mental Hospital system. In 1936, Nolan DC Lewis, professor of neurology in the Neurological Institute, became the first academic to lead PI. He, in turn, was followed by Lawrence C. Kolb in 1954. The Psychiatric Institute innovated at all points on the treatment spectrum: In 1942, a Department of Research Psychiatry was created, with Eugene Barrera and Bernard Pacella, its main members. In 1945, a Psychoanalytic Center for Training and Research was founded, the first official psychiatric training institute to be established in a medical school. Despite the massive interest at PI in psychoanalysis, early in the 1950s, a small number of investigators led by Philip Polatin became involved in psychopharmaceutical trials; by 1956, the Institute had a department of experimental psychiatry, now led by Sidney Malitz, located at the Vanderbilt Clinic.

PI benefited greatly from the tumult of the century, giving refuge to many distinguished scientists and clinicians fleeing the Holocaust. Among the members of the informal “European Club” were Lothar Kalinowsky (from Germany and Italy), the padrone of electroconvulsive therapy (ECT) in the United States; neurochemist Heinrich B. Waelsch (Prague); Paul Hoch (Hungary and Germany), who headed experimental psychiatry and coined the diagnosis “pseudoneurotic schizophrenia”; Sandor Rado (Hungary) who became a leader of psychoanalysis in the New World; Armando Ferraro (Italy), who headed neuropathology at PI. Eric Kandel, who established the Center for Neurobiology and Behavior in 1974, was born in Vienna and later (2000) won a Nobel Prize.

The East Coast

WASHINGTON DC: THE NATIONAL INSTITUTE OF MENTAL HEALTH. The NIMH, funded by the federal government as one of the National Institutes of Health, is not a degree-granting institution, but it is very academic, encouraging original research both in-house, in the "intramural program," and by funding "extramural" psychiatric research across North America. The involvement of the federal government with psychiatric research began in 1929 with the founding of the Narcotics Division of the Public Health Service, renamed Division of Mental Hygiene in 1930. Lawrence Kolb became the chief PHS officer in charge of the division of mental hygiene, and on his retirement in 1944, he had wished to set up a national neuropsychiatric institute (NPI) within the National Institute of Health (NIH). This became possible in 1946 when the National Mental Health Act called for the creation of a National Institute of Mental Health with an in-house research program. NIMH opened its doors in 1949, and Robert Felix, who had succeeded Kolb as director of mental hygiene, became the institute's inaugural director in 1951, with physiologist Seymour Kety in charge of research.

In 1953, the first clinical NIMH ward opened at the Clinical Center for the NIH; there followed in 1955 the Laboratory of Clinical Science and in 1956 the Psychopharmacology Service Center, which in 1960 organized the Early Clinical Drug Evaluation Program, Jonathan Cole, its director. The program became a great engine of progress, conducting investigational trials in the 35 Early Clinical Drug Evaluation Units (ECDEUs) that came to be established by 1969. By 1982, among the 100 investigators most frequently cited in scientific research worldwide, 9 were in the NIMH intramural program.

JOHNS HOPKINS UNIVERSITY: THE PHIPPS PSYCHIATRIC CLINIC. Psychiatry at Johns Hopkins began in 1910 when Adolf Meyer was hired from the Pathological (later Psychiatric) Institute of the New York State Hospitals to become the inaugural professor of psychiatry and director of the new university psychiatric hospital, the Phipps Clinic, funded by Henry Phipps, which opened its doors in 1913. On his retirement in 1941, Meyer was succeeded by Nebraskan John Whitehorn in office until 1960. In these years, Rockefeller Foundation grants brought many young European psychiatrists to the Phipps to study, and it was through them that Meyer's international influence became considerable.

MCLEAN HOSPITAL (CONTINUED FROM ABOVE). In 1888, profiting from the scientific boom then sweeping U.S. psychiatry, a pathology department was organized at the McLean asylum. In 1895, the institution removed from Charlestown to Waverley (Belmont), a suburb of Boston, and was named McLean Hospital. Swiss-born August Hoch, who would shortly study with Kraepelin and Alzheimer, became leader of a chemical laboratory in 1893; Hoch became an early advocate of the new neurohistopathology; a psychology laboratory followed in 1904. After 1955, in keeping with the changing times, the hospital pioneered in the U.S. concepts of the therapeutic community under Alfred H. Stanton.

But biology lay waiting. In 1972, the “transformation of McLean,” as Alan Schatzberg later put it, began when Shervert Frazier, who had also qualified as an internist, came up from Columbia University to become a director. He recruited psychotherapist John Gunderson in 1973, who became the “borderline” specialist; Jonathan Cole and Schatzberg came in 1974 to work in depression; there arrived as well from Massachusetts General Hospital (the parent organization), Joseph Lipinsky in 1974, and Seymour Kety and Ross Baldessarini in 1977. Schatzberg said, “He recruited outstanding people and built the Mailman Research Center, an unbelievably vibrant place.”

HARVARD UNIVERSITY. The Department of Psychiatry at Harvard was founded in 1920 when Adolf Meyer’s student, the Scottish-born Charles Macfie Campbell, left the Phipps Clinic in Baltimore to become director of the Boston Psychopathic Hospital and the inaugural professor of psychiatry at Harvard. Like his mentor, Campbell leaned toward “psychobiology” and psychoanalysis. The influential post at Harvard, however, is chief of psychiatry at the Massachusetts General Hospital, one of Harvard’s teaching hospitals (of which McLean was administratively a part). This post was initially held in 1934 by Stanley Cobb, professor of neuropathology and previously director of the Harvard Neurological Unit at the Boston City Hospital. Some consider Cobb the founder of biologic approaches to psychiatry in the United States. Among

Cobb's successors were Erich Lindemann in 1955, John Nemiah in 1965, and Leon Eisenberg in 1967.

THE INSTITUTE OF LIVING (CONTINUED FROM ABOVE). In 1931, when C. Charles Burlingame was appointed superintendent, what was then the Neuropsychiatric Institute of the Hartford Retreat was in a downhill slide. Burlingame effected a revival, establishing a school of nursing, bringing in recognized figures on staff (to regain the lost accreditation), and, later in the 1930s, implementing the new "shock" therapies. In 1943, the name was changed to the Institute of Living. In 1946, Francis J. Braceland, who had studied at the Zurich University Psychiatric Hospital and the National Hospital for Nervous Diseases in London, became chief psychiatrist. (Braceland is also remembered for being a special witness at the Nuremberg Trials in 1946, whose testimony saved Rudolph Hess from execution.) Said a New York Times obituary in 1985, Braceland is "credited with changing its reputation [Institute of Living] from that of a plush sanitarium for the rich and famous to that of a highly respected psychiatric hospital for the seriously ill." In 1994, the Institute of Living became part of Hartford Hospital.

YALE UNIVERSITY. Yale had the third university department of psychiatry in the United States—after Johns Hopkins and Harvard. The central figure here was Dean Milton C. Winternitz, a neuropathologist who conceived the Institute for Human Relations, which opened in 1931. (The department of psychiatry was situated in the Institute.) Winternitz said in 1925 of the proposed Institute, "… All of these disciplines primarily interested in the problems of human behavior from the standpoint of investigation, graduate teaching, and application, i.e., therapy, [should] be brought together geographically in a single building designed to allow the greatest possible latitude for … cooperation." An embryo department of psychiatry had come to life in the 1920s. Yet only in 1930 was it led by a significant figure, when Eugen Kahn, a Kraepelin student, and collaborator with Ernst Rüdin in schizophrenia genetics, became chair and the first Stirling

Professor in psychiatry. He was followed in 1950 by another eminent Central European, Vienna's Friedrich ("Fritz") Redlich.

In 1911, Arnold Gesell created the Child Study Center at Yale, later associated with several departments, including psychiatry.

Elsewhere

CHICAGO. Chicago had a long tradition of contributions to psychiatry. In 1925, physiologist Nathaniel Kleitman organized a sleep laboratory at the University of Chicago, and from this lab emerged in 1953 a classic paper in Science co-written by Kleitman's student Eugene Aserinsky on rapid eye movement (REM) sleep. Neurologist and psychiatrist Percival Bailey had cofounded in 1946 the Society of Biological Psychiatry. And Laszlo von Meduna, the originator of convulsive therapy, arrived in Chicago from Budapest in 1939 and ultimately found a berth at the NPI of the University of Illinois.

Yet the founding figure in psychiatry is Roy Richard Grinker, who had a background both in psychoanalysis (worked with Freud in Vienna in the early 1930s) and in neurology. Grinker's career at the University of Chicago began in 1933, with his appointment as associate professor of neurology; he became associate professor of psychiatry in 1936, which established psychiatry within the department of medicine (Grinker's appointment at Michael Reese Hospital in 1936 is recalled as "taking over the department of neurology"). In 1955, psychiatry changed to a department in its own right, its first chair C Knight Aldrich. Although psychodynamics was then the watchword in Chicago, the University was not hesitant to appoint in 1966 the elfin Daniel X. Freedman from Yale as the next chair. Freedman, an enthusiastic promoter of biologic psychiatry, became chief editor of the AMA's Archives of General Psychiatry in 1970. He was succeeded as chair by Stuart C. Yudofsky in 1988 and Elliot S. Gershon in 1998. Steven Paul, who later led neuroscience research at Eli Lilly, recalled in a 2011 interview his years in the mid-1970s as a resident in psychiatry at the University of Chicago, "It was a very exciting department in those days. Herb Meltzer [biologic psychiatrist] was there and Heinz Kohut, the analyst, Bob Schuster [Charles R. Schuster, who founded the University of Chicago's Drug Abuse Research Center], and many others. A tremendous department Danny had pulled together, a small but extraordinarily fine department." Meanwhile, in 1974 Philip Holzman, professor of psychology at the University of Chicago, reported a major biologic abnormality in schizophrenia, saccadic eye-tracking movements (smooth-pursuit in tracking is normal).

UNIVERSITY OF NORTH CAROLINA. The Department of Psychiatry at the University of North Carolina (UNC) at Chapel Hill was founded by Chicago psychoanalyst George Ham in 1951. It started to become a biologic piston with the arrival in 1954 of Scotsman John Ewing as clinical instructor, then chair in 1962. Psychiatric endocrinologist Morris Lipton from the University of Chicago joined the department in 1959 and proceeded to steer it toward the endocrinologic hormones that science was just discovering. (Lipton became known as having "opened up the peptides.") Arthur Prange, who had trained at UNC, joined the staff in 1960 and proceeded to solidify UNC's growing association with psychiatric endocrinology. William McKinney (later at the University of Wisconsin) trained at UNC in the mid-1960s, and in his class were Frederick Goodwin (later an NIMH star), the Englishman Peter Whybrow (later chair of psychiatry at the UCLA NPI), and Joseph Mendels (who ended up leading biologic psychiatry at the University of Pennsylvania).

DUKE UNIVERSITY. Across the way from UNC lay Duke University in Durham. In 1953, Ewald Busse, psychoanalyst and geriatrician, became the founding chair of psychiatry at Duke. His successors H. Keith Brodie (1974 to 1982) and Bernard Carroll (1983 to 1990), ended this Freudian spin (in 1968, Australian-born Carroll introduced the dexamethasone suppression test [DST] into psychiatry for the diagnosis of melancholic depression). Duke and UNC together constituted a powerful core of psychiatric research for the southeast.

UNIVERSITY OF PENNSYLVANIA. Psychiatry at the University of Pennsylvania had begun in 1793, when Benjamin Rush, a professor of chemistry, opened a ward for insane patients at Pennsylvania Hospital. But academic psychiatry at Penn really began only in 1874, with the establishment of the Hospital of the University of Pennsylvania. A department of mental diseases received its inaugural head in 1883, and in 1901, Charles Burr was appointed Penn's first chair of mental diseases.

Karl Rickels founded the Clinical Psychopharmacology Unit in 1959. And the Center for Mental Health Policy and Services Research (CMHPSR) was established in 1986.

THE "PSYCHOPATHIC HOSPITALS". Emblematic of the new association between asylum and academy were the so-called "psychopathic hospitals," which began life in the 1880s as reception wards for newly admitted, or "acute," patients. American psychiatrists visiting Europe had learned much about humane care and the usefulness of setting these acutely ill patients aside from the chronic patients working in the farm colonies or vegetating in the back wards. (Indeed, the spotlight began to turn toward creating psychiatric wards in general hospitals, such as "Pavilion F," founded in 1902, of Albany Hospital.)

In 1901, the Michigan legislature appropriated a sum for the establishment of a "psychopathic hospital" on the grounds of the State University of Michigan, as an additional ward of the University Hospital. It was not part of the state asylum system and was entirely under the control of the university. The psychopathic hospital did not, in fact, open until 1906, under the direction of neuropathologist Albert M. Barrett.

In Massachusetts in 1912, a psychopathic hospital opened on Fenwood Road in Boston as a department of the Boston State Hospital in Dorchester; it was under Elmer E. Southard, a professor of neuropathology at Harvard. The plan was, as Henry Hurd in his great 1916 work *The Institutional Care of the Insane* put it, to establish "a hospital for the first care and observation of mental patients and the treatment of acute and curable mental diseases and for an out-patient department … for scientific research as to the nature, causes and results of insanity.” The patients were given laboratory tests, stabilized with hydrotherapy, and then either discharged as recovered or forwarded to the main wards of the state hospital. In 1920, the institution was renamed Boston Psychopathic Hospital under C. Macfie Campbell. In 1956, the name was changed again to Massachusetts Mental Health Center. Several prominent figures in U.S. psychiatry served there, including Abraham Myerson.

Fourteen further psychopathic hospitals were founded by the First World War, although their missions ranged from the conduct of research, as at the University of Michigan and Harvard’s Boston Psychopathic, to the mere reception and detention of acute patients. (On the Iowa Psychopathic Hospital, opened in 1921, see below.)

Mississippi Valley Psychiatry. A string of important psychiatry departments ran down the Mississippi valley and played a crucial role in bringing the new biologic psychiatry to the United States.

UNIVERSITY OF IOWA. Academic psychiatry began in Iowa City with the opening of the Iowa State Psychopathic Hospital in 1921 under the state board of education. The director was simultaneously chair of psychiatry at the university, and the Iowa Psychopathic is considered the first university-affiliated psychiatric department west of the Mississippi. Under the founding director, Samuel T. Orton, in 1919, a neuropathologist who previously had been clinical director of the Worcester State Hospital in Massachusetts, the department rose to become one of the powerhouses of U.S. psychiatry. Jacques Gottlieb, whose background was in neuroendocrinology and who established the effectiveness of the amphetamines in the treatment of depression, taught at the Psychopathic Hospital from 1937 to 1940, then returned to Iowa as professor of psychiatry from 1947 to 1953 before moving on. Erich Lindemann came from Heidelberg to train at Iowa in 1927 and was on staff until 1935, before accepting a post at Harvard. While at Iowa, Lindemann was among the first to investigate the effects of psychopharmaceuticals. (Lindemann is also remembered for helping pioneer the diagnosis of traumatic stress with his 1944 study of “acute grief” in the survivors of the Cocoanut Grove Fire in 1942 in Boston.) Establishing a strong bridge between Iowa and Washington University in St. Louis, George Winokur came from Wash U in 1971 to chair psychiatry at Iowa. William Coryell followed in 1977. Ming Tsuang trained in psychiatry at Iowa then served as professor from 1975 to 1982. In 1996, Winokur and Tsuang (who by now had become the Stanley Cobb Professor of Psychiatry at Harvard) published *The Natural History of Mania, Depression, and Schizophrenia*, based on the research panel “the Iowa 500.” In 1971, Nancy Andreasen completed her training at Iowa, then, while on staff, went on to pioneer the neuroimaging of schizophrenia.

WASHINGTON UNIVERSITY IN ST. LOUIS. Psychiatry at “Wash U” began in 1918, under Sidney Schwab, who headed the division of neurology and psychiatry, a “subdepartment” of the Department of Medicine. In 1938, the Department of Neuropsychiatry became an independent unit under David M. Rioch, who passed the torch to Edwin Gildea in 1942. In 1948, Harvard-trained Eli Robins became a fellow at Wash U, joining the department in 1951. Meanwhile, in 1950 Samuel Guze joined the department, and for the next 20 years, the names Robins and Guze would be closely associated with the growth of psychiatry at Wash U as it became the premier department of biologic psychiatry in the United States. In 1970, they suggested the “medical model” as an alternative to the “biopsychosocial model,” as a motor for delineating disease.

Wash U was also one of the two seedbeds (Columbia the other) of the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders* (DSM). Recalled Paula Clayton in an interview, who at the time was a resident, “We all read Kraepelin. He was our bible.” Under Eli Robins (chair 1963 to 1975) and Samuel Guze (“Goo-zay,” chair 1975 to 1989), psychiatry at Wash U opened up a series of links between basic biology and clinical psychiatry. “[It] was nearer to being a mini-NIMH,” said geneticist Irving Gottesman later, “where under one roof you could have MDs and PhDs of all sorts working together on projects.” Graduates of Wash U assumed important leadership roles throughout U.S. psychiatry. It was the consummate insiders' group and displaced the previous insiders' group, the psychoanalytically oriented Group for the Advancement of Psychiatry (GAP).

Tennessee. Frank H. Luton became the first psychiatrist at Vanderbilt in Nashville, Tennessee, when he returned in 1931, after training at Johns Hopkins under Adolf Meyer. The School of Medicine created a department of psychiatry in 1947 with the appointment of William F. Orr, Jr, who in turn was succeeded by Marc Hollender in 1969, and Michael H. Ebert in 1983. Interest at Vanderbilt passed from dynamic psychiatry to psychopharmacology in the 1970s, with the appointment of such investigators as Fridolin Sulser, Thomas Ban, and Herbert Meltzer.

Meanwhile, in Memphis, Hagop Akiskal, a graduate in 1969 of the medical school of the American University of Beirut, had organized in 1973 an affective disease clinic at the University of Tennessee, one of the first in the United States. From 1987, Akiskal propagated the idea of a "soft bipolar spectrum," heavily dependent on temperament and managed with mood stabilizers rather than conventional "antidepressants."

Tulane. Psychiatry at Tulane in New Orleans was founded by Robert G. Heath after he arrived from Columbia in 1949. In New York, Heath had trained in both neurology and psychoanalysis and established a psychoanalysis program at Tulane. But his real interest lay in the possible metabolic origins of schizophrenia. The charismatic Heath, whom Time magazine called "the Gregory Peck of psychiatry," set out to investigate intracerebral events by persuading doubtful colleagues of the wisdom of inserting indwelling electrodes. This controversial program came to nothing, but Health had several important students. In 1960, one of them, Donald M. Gallant, won for the department of psychiatry a federal grant from the ECDEU of the National Institute of Mental Health, a program that aided the introduction of psychopharmacology into American psychiatry (see above). Gallant became chair in 1969 following

Heath and expanded the entire range of research in psychopharmacology so that it became the flagship program of the Deep South in this area.

The West Coast. Several departments of international distinction on the West Coast were founded—much later than those in other parts of the country. Yet, they are part of the story of the transition from asylum to university psychiatric hospital.

STANFORD UNIVERSITY, PALO ALTO. Psychiatry at Stanford was founded in 1933 when George S. Johnson came from his post at the University of Colorado to become chair of neuropsychiatry. In 1954, neurology split from psychiatry, and Johnson continued as chair of psychiatry. Child and adolescent psychiatry, which was established in 1939, merged with the department in 1957. In 1960, Stanford University School of Medicine moved from San Francisco to Palo Alto, where it quickly became a research-oriented medical school. David Hamburg came from the NIMH in 1961 to chair the department, and he recruited a number of future leaders, such as William Dement, who founded sleep medicine as a clinical discipline as well as a research program; Jack Barchas, remembered for early work on the enkephalins and endorphins; and Helena Kraemer, who developed statistical research methods.

The department went on to become one of the main forces in U.S. psychiatry. Alan Schatzberg, a leader in psychopharmacology and coauthor with Charles Nemeroff of Textbook of Psychopharmacology (1998), came from McLean Hospital to serve as chair from 1991 to 2010. His own work centered on the adverse effects of hypercortisolemia and the development of glucocorticoid antagonists as treatments for psychosis. Laura Roberts, a leader in academic psychiatry and bioethics, was recruited from the Medical College of Wisconsin to serve as chair beginning in 2010.

LANGLEY PORTER CLINIC SAN FRANCISCO. In San Francisco, the Langley Porter Clinic, named after Dean Robert Langley Porter, who conceived it in the late 1930s, opened its doors in 1942 as a 100-bed psychiatric hospital. It later changed its name to the “Langley Porter Neuropsychiatric Institute” and then again to “Langley Porter Psychiatric Institute.” Writes historian Jurgen Ruesch in 1978, “It was based upon the idea that prevention, teaching, and research … would be enhanced if the wealth of clinical experience gained from the approximately 29,000 patients then available in the nine California state hospitals could be combined with the expertise of the staff of a medical school.” The inaugural director was Carl M. Bowman, who simultaneously became the first chair of the new division of psychiatry in the School of Medicine. Bowman was among the charter members in 1946, of the Society of Biological Psychiatry. In 1973, the hospital was transferred from the jurisdiction of the state to the University of California (as was the NPI in Los Angeles [see below]).

NEUROPSYCHIATRIC INSTITUTE LOS ANGELES. The UCLA was opened only in 1947, and Stafford Warren, the inaugural Dean, was said to have “dreamed of creating a ‘Langley Porter of the South.’” Norman Brill was brought from Georgetown in 1953 to become the founding chair of the Psychiatry Department, and in 1961, the first patients were admitted to the new NPI funded by the state government of California. A nearby Brain Research Institute also opened in 1961. Louis J. (“Jolly”) West came from the University of Oklahoma to chair the young psychiatry department, and West built staff from all around the world. In 1959, John French became the founding director of the Brain Research Institute. In 1973, the California State Department of Mental Hygiene transferred the NPI to the University of California, where it became part of the UCLA Health Sciences Center.

DIAGNOSIS

The two great arms of clinical psychiatry are diagnosis and treatment. The following sections are devoted to the histories of both.

Modern psychiatric diagnosis really begins with Philippe Pinel in Paris (see above), who in the second edition of his textbook in 1809 enumerated four psychiatric diseases: (1) “mania, or general psychosis [délire]”; (2) “melancholia, or a specific delusion”; (3) “dementia, or abolition of thought”; (4) “idiotism, or the obliteration of the intellectual and affective faculties.” What he meant by these would parse into a number of distinct modern illnesses, but the point is that he did recognize several specific forms of previously undifferentiated “madness.”

After Pinel and Esquirol (see above), the most important figure in the history of nosology is Emil Kraepelin (“Krep-uh-leen”), professor of psychiatry in Heidelberg from 1891, in Munich from 1903, and author in 1883 of the influential psychiatric textbook, Psychiatry: a Textbook for Students and Physicians (*Psychiatrie: ein Lehrbuch für Studierende und Aerzte*), which reached international influence with its fourth edition in 1893 and became worldwide the dominant voice in psychiatry by the eighth edition, completed in 1915. Kraepelin had little patience with psychiatric theory or with pathologic anatomy and placed the diagnostic interest in psychiatry squarely on the clinical side, meaning at the bedside, especially on the course and outcome of the patient’s illness.

Kraepelin was the clinician’s clinician. On the basis of clinical course, Kraepelin said in 1899 that the two specific diseases in psychiatry were “manic-depressive insanity,” a mood disorder, and “dementia praecox,” or the dementia of adolescence, a thought disorder later called “schizophrenia.” He erected a firewall between them, one that still exists today, as in the DSM system, the cardinal disorders are “major depression,” as opposed to “schizophrenia.” No other historical figure in psychiatry, including Freud, has had the influence of Kraepelin upon contemporary psychiatry, although under the influence of psychoanalysis, U.S. interest in diagnosis did wane for several decades. Henri Ellenberger, a Swiss psychiatrist transplanted to Montreal, recalled in 1955, “I remember the consternation of a German psychiatrist hearing that certain American colleagues consider manic-depressive psychosis as a form of schizophrenia; for him, this was about as fantastic as the assumption that a camel is a subspecies of the elephant.”

A page was turned with the advent of a distinctively American system of classification in 1945, the *Nomenclature of Psychiatric Disorders and Reactions*, which appeared as *War Department Technical Bulletin, Medical 203.* Spearheaded by psychoanalyst William Menninger, the head of consultation psychiatry in the U.S. Army during the war, "Medical 203" made wide use of psychoanalytic insights and underpinned the first effort of the American Psychiatric Association to classify illness, the *Diagnostic and Statistical Manual,* or "DSM-I" (the so-called subsequently) in 1952. (The APA itself was founded in 1844 as The Association of Medical Superintendents of American Institutions for the Insane, becoming the American Medico-Psychological Association in 1894 and the American Psychiatric Association in 1921.)

An even more psychoanalytically oriented volume, DSM-II, emerged in 1968.

In the 1970s, the APA drew up a new task force to make what were intended to be minor changes in DSM to bring it into accordance with the *International Classification of Diseases* (ICD) of the World Health Organization, appointing Robert Spitzer at the New York State Psychiatric Institute to lead it. Spitzer, however, disliked psychoanalysis and wanted a complete revision of the nosology to remove Freudian influences. In 1980 the revolutionary DSM-III emerged, which created such diagnoses as "major depression" and "attention deficit disorder" and anchored "bipolar disorder" firmly in the American classification. The subsequent editions of DSM—DSM-III-R in 1987, DSM-IV in 1994, and DSM-5 in 2013—changed little of this architecture, though in launching "bipolar two disorder" in 1994, DSM-IV did touch off an epidemic of "bipolar" in the pediatric population.

A rival system was the ICD of the World Health Organization. In 1938, an "international revision" conference of the League of Nations decided to add morbidity to its long-standing classification of mortality, and in 1948 the newly founded World Health Organization issued the "sixth revision" of the international lists (ICD-6). It contained such diagnoses as "delusional" insanity (other major psychiatric illnesses were cataloged under “dementia”). A distinct section on “mental disorders” was added in the ninth edition in 1975.

Over the years, the number of diagnoses in psychiatry has skyrocketed from four in Pinel to some three hundred in DSM-5. Some of these diagnoses may not stand the test of time. Yet, on a historical basis, several diagnoses do stand out as enduring and doubtless represent phenotypes of genuine underlying psychiatric diseases.

Specific Diagnoses

Melancholia. Melancholia, as distinct from generic “depression,” is one of the oldest diagnoses in medicine and goes back to the Ancients. Before the 19th century, melancholia tended to be an umbrella term for several varieties of psychosis and mood disorders that today would be recognized as distinct. Yet, at its core, melancholia has always stood for severe depressive mood disorder involving deep sadness, pervasive anhedonia, and psychomotor change, usually in the direction of slowing, but there is an anxious form of melancholia involving psychomotor acceleration as well. Timothie Bright, a Cambridge physician, in his 1586 book *A Treatise of Melancholie* described,

> the sorrowful humor which breeds in them … Of pace, they are for the most part slow … both by their members not so nimble for motion, and the mind occupied with cogitation stays [slows] the pace … Moreover, they are given to weeping sometimes … sighing, sobbing, lamentation, countenance demisse [downcast] and lowering.” Bright left a poignant image of weeping in melancholia, “It blears the eyes and makes the cheeks red; it causes the head to ache, the nose to run, and the mouth to flauer [labor], the lips to tremble; it interrupts the speech and shakes the whole chest with sighs and sobs.

In the 19th century, melancholia became differentiated from other kinds of depressive illness. Among the first to make this distinction was Richard von Krafft-Ebing in 1867, at the time a staff psychiatrist at the Illenau asylum (later, professor of psychiatry in Vienna). Krafft-Ebing distinguished between “simple depression of mood” (*die einfache Gemüthsdepression*) and severe depressions with anxiety and psychosis, including melancholia. The definitive distinction between “melancholia” and “depression” was ventured by Copenhagen psychiatrist Carl Georg Lange in his book on “periodic depressions” in 1886 (translated into German in 1892), which described these milder cases as distinct from (psychotic) melancholia.

The term “melancholia” went out of style around 1900 as Emil Kraepelin substituted “depression” for it, and Sigmund Freud decided that the depressive disorders did not qualify as the main psychoneuroses that psychoanalysis should be addressing. (But see above on a United States interested in “depressive neurosis.”) In recent decades, there has been a revival of interest in melancholia, as the field has begun to differentiate the heterogeneous basin of “major depression” on the basis of treatment response.

Psychotic Depression. In classical psychiatry, much melancholia was psychotic, and little was made of the distinction between psychotic and nonpsychotic. The difference later seemed unimportant because both groups responded equally well to ECT, introduced in 1938. Yet with the growing stigmatization of ECT after the 1960s, depression became treatable primarily with drugs, and in 1975, Alexander (Sandy) Glassman at the New York State Psychiatric Institute discovered that psychotic depression responded poorly to the standard tricyclic antidepressants (TCAs). Four years later, David Avery and Aldo Lubrano at the Palo Alto Veterans Hospital reported that psychotically depressed patients responded better to ECT than did nonpsychotically depressed. Under the leadership of Max Fink at the Stony Brook Campus of the State University of New York, ECT became defined as the most effective treatment of psychotic depression. Despite this evidence of differential responsiveness, psychotic depression continued to be downgraded as a mere “specifier” in the DSM.

Mania. Mania has undergone several transformations. For Pinel and the generations before him, it meant agitated dementia (“raving madness”). With François Fodéré in Strasbourg (1817), unbridled unreasoning outbursts became “furious mania.” In 1858, London psychiatrist Daniel Hack Tuke steered mania in the direction of an affective disorder rather than a disorder of intellect. “Although mania, in many instances, is prolonged anger, it may, likewise, be altogether pleasurable in its manifestations, presenting a condition of exhilaration and uncontrollable excitement, which is rather an excess of joy than of anger.” Then in 1881, Emanuel Ernst Mendel, senior lecturer in Berlin, anchored the term “hypomania” in the nosology, meaning elated mood, pressured speech, and increased motor activity. Mania entered DSM intact in 1952, and hypomania became official in 1994 in DSM-IV as “Bipolar II Disorder.”

Catatonia. Although individual symptoms of catatonia, such as waxy flexibility, had been described for centuries, catatonia as a clinical syndrome was recognized by Karl Kahlbaum only in 1874. Its independent existence was short, as in 1899, in the sixth edition of his Textbook, Kraepelin made it a “subtype” of schizophrenia, and for the next century, catatonia languished as an independent entity because, often when clinicians encountered it, they realized they were not dealing with schizophrenia and called it something else, or ignored it. In 1930, William Bleckwenn at the University of Wisconsin reported that catatonia responded to barbiturates, though this discovery was not widely appreciated. Karl Heinz Stauder, at the Munich University Psychiatric Hospital, described in 1934 a fatal version of catatonia, associated with hyperpyrexia.

The return of catatonia as an independent diagnosis separate from schizophrenia began in the 1970s. In 1976, Richard Abrams and Michael Alan Taylor at New York Medical College identified 20% of a sample of patients admitted to the psychiatric unit of a New York City hospital as having one more catatonia signs. Only 4 of the 55 satisfied the criteria for schizophrenia, while more than two-thirds had affective disorders, usually mania. In the context of growing interest in catatonia as independent of schizophrenia, in 1983, Gregory Fricchione at Stony Brook recommended benzodiazepines, especially lorazepam, in the treatment of catatonia instead of barbiturates. Various syndromes previously seen as separate began to be recognized as catatonic in nature: In 1996, it was suggested that toxic serotonin syndrome (TSS) might be a form of catatonia. A symposium at the American Psychiatric Association meeting in 2000 concluded that neuroleptic malignant syndrome (NMS) and malignant catatonia were the same. In 2011, Dirk Dhossche at the University of Mississippi and colleagues raised the possibility that anti-NMDA receptor encephalitis was a form of catatonia. The American Psychiatric Association responded to this series of new catatonia findings by making catatonia a virtually independent disease entity in the DSM-5 published in 2013.

Delusional Disorders

Delusional disorders, meaning fixed, systematic false beliefs, were recognized in 1816 with Etienne Esquirol's "monomania." He said that the psychosis (*délire*) is fixed on one object alone. As early as 1865, then definitively in 1874, Ludwig DC Snell, director of the asylum in Hildesheim, Germany, distinguished between primary and secondary delusions (*Wahn*), primary meaning fixed, false ideas not caused by another illness and not deteriorating; vague secondary delusions could lead to "the collapse of the entire psychic life," something Snell observed in the kind of illness later called "schizophrenia." This was the beginning of separating delusional disorders from chronic deteriorating psychosis as the former were false beliefs that were fixed, systematic, and did not affect other areas of intellectual functioning.

Anxiety. The term "anxiety" has long been used in psychiatry. In 1769, a young medical graduate of Leiden University ventured a dissertation on "Anxietate," and the term was clearly current among his professors. Yet, the German clinical tradition of the 19th century frowned on anxiety as an independent diagnosis. In Emil Kraepelin's big textbook, there is no freestanding "anxiety" disorder. But it was not just Kraepelinian obdurance. The "anxiety" entry in Daniel Hack Tuke's *Dictionary of Psychological Medicine* (1892) is only two sentences long. What placed anxiety in the center of psychiatry's radar was Freud's belief that anxiety was the basic motor of symptom formation: anxiety arose as a result of intrapsychic conflict over various drives. The entries for "anxiety" (*Angst*) in the general index of Freud's writings extended for eleven pages ("genitals," by contrast, only for four). Accordingly, anxiety has always assumed a disproportionate role in psychoanalytically oriented American psychiatry (mixed anxiety-depression has tended to loom more prominently for the British). DSM-I in 1952 prefaced its discussion of "psychoneurotic disorders" by claiming that, "The chief characteristic of these disorders is 'anxiety'…." and in the discussion that followed "anxiety" figured importantly in each, such as "dissociative reaction," "obsessive-compulsive reaction," and so forth. DSM-III in 1980, although antipsychoanalytic in inspiration, continued the centrality of anxiety while beginning its fragmentation into specific anxiety disorders, of which there were ten. Subsequent editions of DSM have continued this tradition.

Chronic Primary Psychosis (Schizophrenia). Psychiatry has struggled over the years with chronic deteriorating psychotic illness, leading either to some kind of deficit or to the dissolution of the personality (once called "dementia"). Developments in psychiatry's two major cradles are chronicled separately.

FRANCE. In 1852, Bénédict-Augustin Morel, then at the Maréville asylum in eastern France (but shortly to head the St-Yon asylum outside of Rouen) called such psychoses of adolescent-onset *démence précoce*, or premature dementia (see above). In 1857, he applied the notion of "degeneration," or worsening across the generations, to psychiatric illness (*Traité des Dégéréréscences*) and 1860, in one of the most famous declarations in the history of psychiatry, in his *Treatise on Mental Illness* (*Traité des Maladies Mentales*) he avowed premature dementia in the young to be a consequence of degeneration.

In 1883, Valentin Magnan, a staff psychiatrist at the Sainte-Anne Clinical Asylum in Paris, described "chronic psychosis"—he later added the qualifier "involving systematic evolution"—an often-deteriorating form of psychosis in patients who were not hereditarily predisposed. This remained quite influential in France, though elsewhere, it was eclipsed by “schizophrenia” (see below).

French experimentation with chronic psychosis continued, even as Magnan’s degeneration-based doctrines were discredited, and in 1910, Maurice Dide, at a psychiatric hospital in Toulouse, proposed “chronic hallucinatory psychosis,” which, though severe, did not deteriorate. To this day, the concept has remained influential in France without reaching a larger international audience.

GERMANY. Meanwhile, in Germany, a different approach to chronic psychosis was being elaborated: deterioration to “dementia,” or at least to a severe deficit. In an 1863 book on the classification of psychiatric illness, Karl Kahlbaum, a staff psychiatrist at the East Prussian provincial asylum of Allenberg, differentiated a “deteriorating psychosis,” which he called *Vesania typica*, which ran its course in four stages, the last of which was “dementia.” Vesania was a customary term at the time for chronic psychosis. In 1871, Kahlbaum and his student Ewald Hecker differentiated further a version of this Vesania beginning in adolescence that they called *hebephrenia*. Hebephrenia, like Vesania typica, usually ended in dementia. (Although Hecker’s name appeared alone on the paper, it was understood that the concept was really Kahlbaum’s.)

At this point, a considerable amount of European scholarship, dating from Morel in 1852, had accumulated that linked chronic deteriorating psychosis to onset in adolescence. In 1893, Kraepelin synthesized this literature in a concept that was to sit rock-solid in psychiatry for more than a century: *dementia praecox*. Over the next decade, he identified three subforms of it: hebephrenic, catatonic, and paranoid. They had in common a begin usually in adolescence or young adulthood, and a downhill course to “dementia.” So magisterial was the Kraepelinian synthesis that all previous writing on chronic psychosis became virtually forgotten. In 1908, Eugen Bleuler, professor of psychiatry in Zurich, baptized Kraepelin’s dementia praecox as “schizophrenia,” seeing it as a much milder disease and not linked to adolescence. Bleuler’s schizophrenia remains little changed today, a single deteriorating psychotic disorder that may onset at any point in life and that may well end in “defect” (or social remission), even if “dementia” as the end stage of the illness has stopped being spoken of. In 2013, DSM-5 dispensed with the famous Kraepelinian “subtypes.”

Many “schizophrenia” patients may spend long periods without being actively psychotic; the primary symptoms seem to be emotional blunting with avolition and a formal thought disorder.

Brief Reactive Psychosis or Brief Psychotic Disorder

Chronic psychotic illness had long been seen as something indwelling and constitutional. The alternative notion that psychosis could arise from stress was codified as *la bouffée délirante* by two students of Valentin Magnan at Sainte Anne in Paris in 1886, then by Magnan himself in 1891—who saw it as arising mainly in the “degenerate.” August Wimmer at St. Hans Hospital in Denmark christened it “psychogenic psychosis” in 1916, with an emphasis on reaction rather than degeneration. Then in 1968, Eric Strömgren in Aarhus, Denmark, revived Wimmer’s concept in an influential (in Scandinavia) paper on “reactive psychoses,” a term that he changed in 1974 to “psychogenic psychoses.” In 1980, DSM-III recognized “brief reactive psychosis,” with no reference to any of these other international terms. (These developments are charted in Shorter, *Historical Dictionary*.) The French translation in 1989 of DSM-III-R makes no reference to bouffée délirante and mentions only *psychose reactionnelle brève*, an interesting example of the collapse of these once distinctive national nosologic traditions.

Bipolar Disorder

The “bipolar disorder” of DSM is not Kraepelin’s “manic-depressive insanity,” which Kraepelin insisted included all depressions of whatever polarity, mania, hypomania, and the attendant anxiety. Rather, in his 1948 textbook Karl Leonhard, then in Frankfurt am Main and a student of Karl Kleist (who introduced the concept of *phasic psychoses*, or illnesses that alternate from one state to another), proposed the term “bipolarity” for the alternation of depression and mania as an illness separate from unipolar depression. In 1957, *in The Classification of the Endogenous Psychoses* (*Die Einteilung der endogenen Psychosen*), Leonhard asserted that unipolar depression had a different psychopathology from the bipolar variety. Filled with neologisms and lacking in quantitation, the book had a limited international impact. Yet a small cadre of investigators, such as Frank Fish in England, Helmut Beckmann in Germany, and George Winokur in the United States, became enthusiasts of the Leonhardian notion of bipolar disorder and managed to insert it in the literature, so that by 1980 when DSM-III was published, bipolar disorder was self-understood as a different disease from unipolar depression (in DSM-III called major depression).

Trauma and Its Sequelae

Ever since Napoleon’s disastrous retreat from Moscow in 1812, psychiatry has recognized that symptoms may arise from great stress. (In Napoleon’s case, of an army of 400,000 that set out, 7,000 returned. Along the way, much “nostalgia” was witnessed—an early label for fatal catatonia.) In 1866, London surgeon John Eric Erichsen originated the diagnosis of “railway spine,” vague and nonspecific symptoms supposedly attributable to the “spine” in minor railway mishaps. Carol Moeli, a Berlin psychiatrist, elaborated in 1881 upon the specific psychiatric consequences of such events, penning the first description of what became known as post-traumatic stress disorder (PTSD). In 1881 as well, Berlin neurologist Hermann Oppenheim coined the phrase “traumatic neurosis,” psychiatric and neurologic symptoms arising from shock.

The First World War spawned a whole raft of descriptions of psychological sequelae from combat, of which terms the most lasting has been “shell shock”—from Charles S. Myers in 1915. The Second World War gave birth to “combat fatigue” as a synonym for war neurosis. Meanwhile, a tragic fire in 1942 at the Cocoanut Grove nightclub in Boston gave rise in 1944 to “acute grief” as yet another term for acute stress reaction. Most recently, following a sustained political campaign by the veterans of the Vietnam War—and spearheaded by Yale psychiatrist Rober Lifton—DSM-III in 1980 coined the term “posttraumatic stress disorder.” This diagnosis has been among the most rapidly proliferating in U.S. psychiatry.

Dementia

The dementias have always been a problem for psychiatry, as the field has struggled to differentiate loss of intellectual function from personality deterioration. In 1814, Etienne Esquirol took up the idea of his teacher Pinel of dementia as a distinct disease entity, separate from melancholy, mania, and imbecility. “There exists a very distinctive kind of insanity in which the disorder of ideas, sentiments, and determinations is characterized by the weakness and the more or less pronounced abolition of all the sensory, intellectual and moral faculties.” In particular, Esquirol differentiated senile dementia from other conditions of “weakmindedness.” (Shorter, *Historical Dictionary of Psychiatry*, chronicles developments in dementia.) There followed a long series of differentiations of the organic dementias: Sergei Korsakoff distinguished ethanol-related amnesia (Korsakoff psychosis) from dementia in 1887; Alois Alzheimer distinguished “presenile” dementia from the senile variety in 1906; in 1926, Hugo Spatz, head of neuropathology at the Munich University Psychiatric Clinic, suggested that a distinctive frontal- and temporal-lobe wasting should be called “Pick’s Disease” after Arnold Pick, professor of psychiatry at the German university in Prague, who first reported it in 1892; in 1912, Friedrich Heinrich Lewy described distinctive intracytoplasmic inclusions, later called “Lewy bodies,” which he detected in the brain stem in Parkinsonism; and in 1962, neuropathologist John S. Woodard at the Camarillo State Hospital in California, proposed Lewy-body dementia as a separate form of dementia; in 1948, London psychiatrist Robert Denis Newton codified long-established German thinking that presenile Alzheimer’s and the dementia of senescence represented a single pathologic process, and suggested calling it “Alzheimer’s dementia”; Raymond

Adams at Harvard University and Maurice Victor at Case Western University, emphasized in 1977, that Alzheimer disease was not just an accelerated extension of old age but a pathologic eruption into it.

Ever since New Jersey pathologist Harrison Stanford Martland's paper "Punch Drunk" in 1928, repeated cranial trauma has been considered a distinct cause of dementia. Martland said, "Fighters in whom the early symptoms are well recognized are said by the fans to be 'cuckoo,' 'goofy,' 'cutting paper dolls,' or 'slug nutty.'" Since then, physicians have been alerted to the neuropsychiatric consequences of repeated head trauma. In 1937, in the U.S. Naval Medical Bulletin, naval surgeon J.A. Millspaugh called it *Dementia Pugilistica*. In a paper in the British Medical Journal in 1989, on "Boxing and the brain," John Arthur Nicholas Corsellis pulled this literature together in a red warning light about repeated head trauma. By the new millennium, these concerns about early dementia had been expanded to all sports involving repeated head trauma.

Neurosis

The classic distinction between psychosis and neurosis was abolished in DSM-III in 1980. Neurosis, as a term, is among the oldest in psychiatry; it was introduced by Edinburgh physician and nosologist William Cullen in his *First Lines in the Practice of Physic* in 1777 to mean diseases of the nervous system without an obvious physical lesion. In the next half-century, it came to be synonymous with brain disorder. It was Richard von Krafft-Ebing, in his *Textbook of Psychiatry* (*Lehrbuch der Psychiatrie*) in 1872, who coined the term "psychoneurosis," meaning mental illnesses that affect normal brains (in contrast to brains affected with "degeneration"). Sigmund Freud used the term psychoneurosis for the first time in his writing in 1898. But neurosis had by that time long entered medicine, and Freud proceeded to employ it as a synonym for "disorder." After Freud, neurosis remained largely in the area of psychoanalytic discourse, which was the dominant discourse in psychiatry until DSM-III in 1980.

NEW TECHNIQUES

Psychiatry is not among the most technologic of medical specialties. Yet changes in technique have expanded the range of its knowledge and enhanced the diagnostic and therapeutic abilities of its practitioners.

Epidemiology

The study of epidemiology had an early bump-up with the observation of Thomas Clouston in 1873, in the *Journal of Mental Science* that,

> The wide series of diseases which are at present called insanity prevail more in some places than in others … When one comes to look carefully into the reports of lunatic asylums in different parts of the country it is found that there are forms of brain disease (or varieties of insanity as they are called) present in abundance in one place which have almost no existence in another … This investigation must be very largely conducted on the numerical method. (Clouston TS. The local distribution of insanity and its varieties in England and Wales. *J Ment Sci.* 1873;19(85):1–19, reproduced with permission.)

Yet, it was the Germans who initially picked up this torch. At the German Psychiatric Research Institute (*Deutsche Forschungsanstalt*) in Munich, founded in 1917, by Emil Kraepelin, Swiss psychiatrist and geneticist Ernst Rüdin, inaugural director of the eugenics research institute of the DFA, led studies on psychiatric epidemiology (cross-sectional) and genetics (longitudinal). Unfortunately, in the Third Reich, Rüdin had a particularly unsavory involvement with public policy, arguing for the Nazi racial and sterilization laws, and after 1945 was briefly interned in the United States. This National Socialist involvement of the DFA and other German groups lent to psychiatric epidemiology and genetics a bad odor that retarded the development of the field for decades.

It was in Denmark that Eric Strömgren, the most important psychiatric epidemiologist of the pre-1970 period, flourished. As a student, he visited the Rüdin group in 1935; he undertook in 1938 what became an epidemiologic classic of the small island of Bornholm. He became a professor of psychiatry in 1945 and was instrumental in organizing the Danish Psychiatric Central Registry at Aarhus, which in 1969 became an electronic register of everyone in Denmark admitted to a psychiatric service. By 2011, this famous register contained over 700,000 individuals and more than 3 million treatment episodes. One offshoot of this was the Danish-American cohort study in 1968, led by David Rosenthal, Paul Wender, and Seymour Kety at NIMH. It merged two registers: that of children who had been adopted away and that of admissions to psychiatric hospitals. This remarkable database permitted the NIMH collaborators, together with Fini Schulsinger in Copenhagen and other Danish colleagues, to determine that children adopted from schizophrenia families but raised in normal homes often became schizophrenic. It was a major blow to the "nurture" school. At a conference in Dorado, Puerto Rico, where these results were first presented, Rosenthal said, "The case for heredity has held up convincingly. At the moment, I can see no grounds for withholding affirmation any longer."

In the United States, the National Institute of Mental Health sponsored, in the 1980s, the 5-site Epidemiological Catchment Area (ECA) study, the first to inquire about diseases rather than symptoms, the results of which were reported in 1991. Myrna Weisman at Columbia later said in an interview the big finding of the ECA was that "These disorders begin in the young … often in adolescence, and certainly, by young adulthood … So, the biggest contribution of the ECA was turning the focus on young people and their high rates of psychiatric disorders."

In the early 1990s, NIMH sponsored the National Comorbidity Survey (NCS) to assess the prevalence of DSM-III-R disorders in a nationally representative sample. Early in the new century, the NCS was redone in the National Comorbidity Survey Replication (NCS-R), using the international WHO Composite International Diagnostic Interview to collect DSM-IV diagnoses from a household survey and to make international comparisons possible.

Statistics

Paris psychiatrist Jean-Pierre Falret's critique of the counting method in 1864, in the preface of his On Mental Illness (*Des maladies mentales*), has not lost its relevance today: "Statistics as a procedure are in fact all the more dangerous because they offer all the appearance of truth." Falret scorned the statistics of the day as failing to include homogeneous clinical populations and using abstractions overly divorced from reality. Modern statistical theory, as Bernard Carroll traces events, originated in the last quarter of the 19th century and the first quarter of the 20th century. Regression to the mean was described in 1877; regression and correlation analysis in 1888 by Francis Galton; the Chi-squared test in 1900 was originated by Karl Pearson; the student's t-test in 1908 by W.S. Gossett; the analysis of variance (ANOVA) comes from RA Fisher in 1919; power analysis, confidence intervals, Type I and Type II error originated in the 1930s from Jerzy Neyman and Egon Pearson. But these advances were not incorporated as research tools into the clinical science of psychiatry until well beyond the 1930s.

The early use of statistics in psychiatry consisted essentially in tabular bookkeeping—simple descriptive statistics such as census details, cohort descriptions by age, age of onset, sex, or outcome. Use of statistics to test hypotheses in psychiatry came much later. Emil Kraepelin maintained detailed counting cards (Zählkarten) of cases he observed, leading up to his landmark distinction between dementia praecox and manic depressive insanity (see above). Assen Jablensky's 1993 reanalysis of those cases with modern statistical methods essentially confirmed the existence of two separate disorders that Kraepelin had recognized by informal Gestalt inferential methods. The same cannot be said of Aubrey Lewis, whose 1934 discussion of depressive illness confidently announced a single-dimensional model without the benefit of any statistical analyses. That position became dogma within Maudsley Hospital circles and led to conflict with the Newcastle school under Martin Roth. Eventually, Lewis's primary data were subjected in 1977 to modern statistical analysis by Lesley Kiloh and Roger Garside (two of the original Newcastle group), and they were found actually to support the Newcastle binary model. These two examples illustrate the absence of reliable means to validate the proposals of clinical experts before the entry of statistics into psychiatric research.

Aside from elementary analytic procedures such as group comparisons (in categorical and dimensional versions), significance testing, and correlations (all in parametric and nonparametric versions), the major statistical themes that moved psychiatric research were numerical taxonomy and psychometrics. Derived from advances in basic statistics, these approaches appeared first within academic psychology for the study of personality traits and dimensions of psychopathology. For the most part, they were slow to be taken up within the discipline of psychiatry and, when they were, the history of their adoption is inseparable from the history of clinical assessment instruments that relied on the new statistical approaches. In parallel, innovations in basic statistical theory and technique also were adopted within psychiatry for clinical trials, as well as for epidemiologic and genetic studies.

Factor Analysis and Personality Inventories

Factor analysis originated with Charles Spearman and Raymond Cattell. The psychological sciences adopted the technique in the 1930s. In parallel, the Minnesota Multiphasic Personality Inventory (MMPI) was under development by Starke R. Hathaway and J. Charnley McKinley at the University of Minnesota from the late 1930s. Local use apparently began in 1939. The original published version appeared in *JAMA* in 1943: The MMPI has seen many later revisions. A perceived advantage was casting it as a descriptive and atheoretical approach to personality and psychopathology, not derived from psychoanalytic theory. Over the years, cultural and ethnic biases in the MMPI have been alleged. Nevertheless, it attained widespread use in education, clinical psychology, and employment screening. A scoring innovation for the MMPI was the devising of T-scores—a standardized metric where the mean is set at 50 and the SD at 10. Other scales adopted the same scoring approach, which had the benefit of standardizing responses and allowing cross-scale comparisons. In parallel, Raymond B. Cattell devised in 1946 a personality inventory for which factor analysis was an essential component. His psychometric instrument is famous as the Cattell 16PF personality factors inventory.

Controlled Trials

The first controlled trial in psychiatry was reported in 1922 in the *American Journal of Psychiatry* by Clarence O. Cheney, assistant director of the New York State Psychiatric Institute, then at Ward's Island, and bacteriologist Nicholas Kopeloff. They wanted to establish whether the organ removals (colectomies, teeth, etc.) then in vogue for the treatment of mental illness were, in fact, effective, and to do so, they studied 60 patients with "focal infections" among the general admissions to the Manhattan State Hospital on Ward's Island, dividing them into two groups, the "operated group" receiving operative treatment for their " 'foci' of infection" versus those not so treated (the "control group"). They found, "On the whole, the operated group appears to have received no more benefit than the control group."

Following the tuberculosis studies of Bradford Hill after the Second World War, randomizing the patients to control or treatment groups became increasingly common. The first randomized controlled trial in psychiatry with "blinded" investigators was conducted in 1955 by David Lewis Davies and Michael Shepherd at the Maudsley Hospital, comparing reserpine to placebo in the treatment of "anxious and depressed patients."

The use of probabilistic statistics in psychiatry has a much more recent origin. Four statistics are used to measure the reduction of risk in treatment (two of them compare vs. lack of treatment). (The following discussion cribs from Andreas Laupacis and collaborators, 1988.)

- **The relative risk reduction (i.e., how much risk reduction in percent).** This is the classic measure.
- **The "odds ratio."** A probability (P) of 0.25 (one chance in four) represents odds of 1:3 or 1/3. This is insensitive to a difference in

risk in the absence of therapy. It was introduced by N. Mantel and W. Haenszel in 1959.

- **Absolute risk reduction.** The differences in event rates between the control and treatment groups. A genuine measure of absolute risk reduction but expressed as a decimal, “This measure may be difficult for [physicians] to remember and incorporate into clinical practice,” say Laupacis and colleagues.
- **Number needed to be treated (NTT).** The number of patients who must be treated in order to prevent one adverse event. Laupacis and colleagues proposed this in 1988. “It tells clinicians and patients in more concrete terms how much effort they must expend to prevent one event, thus allowing comparisons …” Although many clinicians will be put off by such exercises, these statistics mark the definitive passage from psychoanalysis with its evidentiary base of anecdotes to modern clinical psychiatry that employs the same evidentiary base as the rest of medicine.

Tests in Psychiatry

Despite protestations that psychiatry “has no diagnostic tests,” there are, in fact, quite a few. In 1906, August Wassermann and colleagues at the University of Berlin described a diagnostic test for “progressive paralysis” (what neurosyphilis was then called) based on the patient’s blood or cerebrospinal fluid. In 1913, Hideo Noguchi, a microbiologist at the Rockefeller Institute for Medical Research, succeeded in obtaining a culture of *Treponema pallidum* in a sample of the brains of neurosyphilitic patients who carried the diagnosis of “general paralysis of the insane,” the English equivalent of “progressive paralysis.” Therewith, neurosyphilis became identified as an infectious disease and passed from the purview of psychiatry, where it had lodged for the previous century. In 1931, Hans Berger in Jena used the EEG, which he had just invented, to confirm a specific pattern of brain waves in a patient with epilepsy. These were early diagnostic tests in psychiatry.

More were to come. A group of researchers led by Charles Bradley at the Emma Pendleton Bradley Home in East Providence, Rhode Island, established in 1938 that a certain subset of children who would later be called “hyperactive” (with the diagnosis of attention-deficit/hyperactivity disorder, ADHD) demonstrated a specific electroencephalographic pattern. The test remains controversial, but it has not been disallowed. In 1940, Mandel Cohen and Stanley Cobb, psychiatrists at Harvard, reported in The Journal of Clinical Investigation that carbon dioxide could precipitate what were later called “panic attacks” in patients prone to anxiety. Abnormalities in serum lactate thus became a biologic marker for panic, and there followed a considerable history of using “panicogens” to study panic.

As early as 1958, “pharmaco-EEG” was used to “classify psychopharmacologic drugs and predict their clinical applications,” as Max Fink, a pioneer of the technique, later put it. Then in 1962, in a study published in the American Journal of Psychiatry, Fink and Donald Klein, part of the Hillside Hospital Experimental Team, established in a proper randomized controlled trial of chlorpromazine and imipramine that depressed patients responded well to imipramine, schizophrenics did not. The imipramine challenge was the first biologic test for serious depression.

Bernard Carroll at the Royal Melbourne Hospital applied the DST in 1968 to confirm the presence of melancholic depression. The DST, based on a dexamethasone challenge to the hypothalamic–pituitary–adrenal (HPA) axis, establishes HPA dysregulation in patients with severe mood disorders. In 1983, Gregory Fricchione and colleagues at Harvard reported that catatonia is responsive to the benzodiazepine lorazepam. In their 2003 book on catatonia, Max Fink and Michael Alan Taylor proposed a one- or two-dose benzodiazepine challenge as a convincing diagnostic test for catatonia. Biologic psychiatry proceeds from the premise that behavioral disorders are symptoms of underlying cerebral dysfunction. It is therefore unsurprising that biochemical markers have long existed in psychiatry.

Convulsive and Coma Therapy

Convulsive therapy, probably the most powerful psychiatric treatment on offer, had its origins in the 1930s, together with the other so-called “physical therapies” that addressed the brain itself.

First of the new physical treatments was insulin coma therapy, introduced in 1930 with the discovery by Manfred Sakel, then an assistant physician in a private nervous clinic in Berlin, that the withdrawal symptoms from morphine addiction could be relieved with insulin. It soon became apparent that the curative agent was an insulin-induced coma, and when, after the Nazi seizure of power in 1933, Sakel returned to his native Vienna, he persuaded the professor of psychiatry, Otto Pötzl, to let him experiment with insulin coma in the treatment of schizophrenia. From this work issued in 1934, a series of articles in a Viennese medical weekly that turned into a book in 1935, *A New Method of Treating Schizophrenia* (*Eine neue Behandlungsmethode der Schizophrenie*). A series of insulin comas does seem to have had a certain effectiveness in relieving the symptoms of chronic psychosis, and insulin remains today an underexplored agent in psychiatry. Some of Sakel’s patients also experienced seizures, and these as well may have been a therapeutic mechanism.

It was Budapest psychiatrist Ladislaus von Meduna who, in 1935, began the systematic exploration of chemically induced cerebral convulsions as a treatment. Meduna initially used camphor to initiate brain seizures, then the heart drug pentylenetetrazol. Meduna experienced extraordinary successes, especially in patients with the symptoms of catatonia, and his 1935 report in the Journal of Combined Psychiatry and Neurology (*Zeitschrift für die gesamte Neurologie und Psychiatrie*) is of historic importance in introducing the concept of therapeutic seizures to psychiatry. Yet many patients resisted chemically induced seizures because of the anxiety they experienced in waiting for the seizure to begin.

In 1938, Rome psychiatry professor Ugo Cerletti hit upon the idea of inducing the seizures with electricity so that the patients were instantly unconscious and underwent no anxious latency period. He quickly discovered that patients with melancholic depression responded readily to ECT, and the technique spread rapidly throughout psychiatry; it was at the time relatively uncontroversial. Cerletti had demonstrated not that convulsive therapy was effective (Meduna's doing) but, as modern ECT-investigator Richard Abrams puts it in his 1988 manual of convulsive therapy, "that such convulsions could be induced safely, reliably, and inexpensively by electrical means." Cerletti and the other early electrotherapists did not restrain their patients, and as a result, the "unmodified" seizures resulted in numerous fractures. To reduce such side effects, curare was first employed as a means of blocking the nerve–muscle junction, then, in 1952, succinylcholine, together with a barbiturate anesthetic. Yet even this modified ECT became in the 1960s an object of opprobrium in the counter-culture and then in the eyes of the pharmaceutical industry, which insisted that psychopharmacology could replace convulsive therapy. But it turned out that ECT offered distinct advantages in the treatment of melancholic depression, mania, and catatonia, and in 1978 the American Psychiatry Association offered an endorsement of it to counter the ballooning stigma caused in particular by the 1975 Hollywood movie, *One Flew Over the Cuckoo's Nest*. Max Fink, at the Stony Brook School of Medicine, led a campaign to rescue ECT from threatened oblivion. In 1990, the APA issued a much more enthusiastic endorsement of ECT, and it would be fair to say (as David Healy and I do in our 2007 history of shock therapy) that ECT has now resumed its prominent place in the panoply of psychiatric treatments.

Neuroimaging

Neuroimaging dates back to Harvey Cushing's 1896 radiograph of the cervical spine of a patient who had just been shot in the neck; the history of neuroimaging includes air encephalography, introduced in 1918 and used in Germany in 1927, to identify enlargements of the ventricular system in patients with schizophrenia. Gerd Huber's classic 1957 monograph *Pneumoencephalography and Psychopathology in the Endogenous Psychoses* (*Pneumooencephalographische und psychopathologische Bilder bei* *endogenen Psychosen*) was probably the high water mark of pneumoencephalography in psychiatry.

Carotid angiography, introduced in 1927, has never had significant psychiatric uses. But radionuclide brain scanning commenced in 1948, showed great promise once radioactive ligands were introduced in the 1970s in the form of single-photon emission tomography (SPECT) and positron emission tomography (PET).

Tom Bolwig, professor of psychiatry at the University of Copenhagen, outlines the following story: Among the earliest studies, in 1974 David H. Ingvar and Göran Franzen at Lund University reported in the Acta Psychiatrica Scandinavica decreased cerebral blood flow in chronic schizophrenia. SPECT and PET were employed in the 1980s to measure regional cerebral blood flow and metabolism and, later, neurotransmitter-binding potential. SPECT and PET are used as well to quantify the regional density of receptors of a given type and receptor-binding displacement. But these methods expose patients to radioligands and demand cyclotron capacity, so they cannot be applied outside of specialized centers. In 1988, Daniel Weinberger and associates at the NIMH employed PET to help develop the "hypofrontality" hypothesis in schizophrenia.

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI) entered medicine in the late 1970s. In psychiatry, the first controlled study using MRI was led by Nancy Andreasen, finding in 1986 in the Archives of General Psychiatry that a population of schizophrenic males had "markedly smaller frontal lobes." Functional MRI (fMRI) examines changes in blood oxygen level, a proxy measure of neural activity. The Yvette Sheline group at Washington University in St. Louis used fMRI in 2002 to demonstrate that long-standing depression produced a decrease in 5-HT(2A) receptors in the hippocampus, a functional finding. Structural MRI measures brain and regional gray and white matter volumes and was used in 2003 by Sheline and colleagues to measure the loss of hippocampal volume in severe untreated depression (the longer untreated, the greater the loss of volume). Thus, in Sheline's terms (in the 2002 article), "Functional imaging extends the sensitivity and specificity of structural imaging."

Brain Connectivity

Brain connectivity refers to a pattern of anatomical links ("anatomical connectivity"), statistical dependencies ("functional connectivity"), or causal interactions ("effective connectivity") between distinct units within the nervous system. Using a variety of MRI and fMRI methodologies, information about the functional and structural integrity of neural circuitry—"neural profiles"—can be provided in healthy and psychiatrically unwell individuals. In 2008, M.L. Phillips and associates identified abnormalities of connectivity in the neural circuitry supporting emotion processing and regulation in bipolar disorder. In 2010, in Biologic Psychiatry, Amelia Versace and colleagues attempted to differentiate unipolar versus bipolar depression on the basis of the functional white matter integrity of the neural circuitry regulating emotion.

Quantitative EEG (QEEG) Brain Mapping

Introduced in the 1980s, the QEEG brain map produces a three-dimensional reconstruction of the brain's activity. Using advanced algorithms, it is possible to identify brain-wave patterns from deep brain structures. The method is noninvasive but has a space resolution weaker than that of the above-mentioned methods. QEEG has been used by ER John and associates to identify activity clusters in a variety of different psychotic states. One reason for the lesser popularity of QEEG compared to SPECT, PET, and MRI may be, as Tom Bolwig observes, "that understanding the elements of electrophysiology seems a bit harder for many physicians than accepting colored spots on an image of the brain." Yet QEEG represents pure neuronal transport and can record immediately and for very long periods of time, which are essential qualities for monitoring chains of events.

THE BEGINNING OF THE SECOND BIOLOGIC PSYCHIATRY

Psychiatry in Europe, with its heavy emphasis on heredity, had always been biologically oriented. But in the 1930s, psychoanalysis in the United States wiped the biologic slate clean. Then in 1946, at a meeting at the Fairmont Hotel in San Francisco, the biologic thread began to re-emerge. Two California physicians—Johannes M. Nielsen, a neurologist at the University of Southern California, and his student, George N. Thompson, chief psychiatrist at the Los Angeles General Hospital, convoked those interested in “the biological basis of behavior.” The meeting was attended by the heavyweights in U.S. neurology and psychiatry: Percival Bailey, a Chicago neurologist; Stanley Cobb, professor of neuropathology at Harvard; and Karl M. Bowman, at the Langley Porter clinic in San Francisco. From this meeting emerged the Society of Biological Psychiatry. In 1947, Nielsen and Thompson published the first textbook of biologic psychiatry in the United States, *The Engrammes of Psychiatry*.

The Revolution in Psychopharmacology

Although the term “psychopharmacology” seems to have been coined by David Macht, a pharmacologist at Johns Hopkins University, in 1920, to describe “the effect of drugs on psychological functions,” it was not until the mid-1950s, with the explosion of interest in mechanisms prompted by the success of the antipsychotics, that the term started to come into use. When Paris psychiatrist Jean Thuillier visited Joel Elkes’s newly founded department of experimental psychiatry in Birmingham in the mid-1950s, he was introduced by Willy Meyer-Gross. (Meyer-Gross, a refugee from Hitlerism who previously had been a mainstay at Heidelberg, was finishing his career in Birmingham as an associate of Elkes.) Meyer-Gross said in the introduction, “From everything that will be said to you this evening, bear in mind this new word: psychopharmacology. We already practise it here without realizing it, and everything we do tomorrow and in the future, everything we will want to do, will be gathered into this new discipline."

There has been much discussion pro and con about psychiatry's turn toward psychopharmacology. For all current concerns about polypharmacy and "cosmetic psychopharmacology," one does well to bear in mind the recollections of Robert Felix, inaugural director of NIMH in 1949, of his days as a resident in a mental hospital in 1931,

> He explained that continuous flow baths were generally used for disturbed patients. "If the patient was too disturbed to lie in the tub, either a hot or a cold pack was used," which, while not specifically identified as such, acted as an effective physical restraint. For agitated patients, whether excited or depressed, "three chemical substances were used: paraldehyde, phenobarbital, or bromide." Felix noted that their bible was chapter XI of Bleuler's Textbook of Psychiatry. 'The Treatment of Mental Diseases in General'

In the years after the Second World War, psychiatry swung on a massive hinge. "There can be no twisted thought without a twisted molecule," wrote Ralph Gerard in 1955 in the American Journal of Psychiatry, keynoting the advent of a new era in psychiatry, the easing away from psychoanalysis, and the turn to pharmacotherapeutics as the main treatment modality. Biology marked, said Gerard 2 years later in Science, "the emphatic re-entry of the brain into the mental arena." In these years, the field evolved from being the lowest prescribing of the medical specialties to the highest. (In 2005, 90.1% of all psychiatric visits ended with a prescription; the next highest was cardiovascular diseases with 85.4%.)

The revolution may have begun with the synthesis in 1938 of lysergic acid diethylamide (LSD) by Sandoz chemist Albert Hofmann. It was in 1943 that Hofmann discovered it was psychoactive; LSD went on to have a brief career in psychotherapy and the treatment of alcoholism, but it generated great scientific curiosity: Was its mechanism identical to that of schizophrenia?

In 1952, the Rhône-Poulenc Laboratories in Paris introduced the first antipsychotic (neuroleptic), chlorpromazine, of the phenothiazine class of three-ringed structures, which was brand-named Largactil in Europe, Thorazine in the United States. The staff of Paris psychiatry professor Jean Delay conducted the initial clinical trials. A number of other phenothiazine antipsychotics followed.

These two compounds—LSD and chlorpromazine—initiated the era of psychopharmacology. As Theodore Sourkes at McGill University, “a biochemist in psychiatry” as he called himself, put it later,

> The neuroleptic action of chlorpromazine and the psychodysleptic action of LSD … held out the promise, on the one hand, of a chemical treatment of mental disorders and, on the other, of exploring the possibility that schizophrenia was caused by a toxic substance. As a consequence, the fifties and sixties of the last century saw the introduction of chemical theories into psychiatry. (Sourkes TL. A biochemist in psychiatry: dropping in on the psychopharmacology era. In: Ban TA, Healy D, Shorter E, eds. *Reflections on Twentieth-Century Psychopharmacology.* Animula Publishing House; 2004:290–298.)

The proliferation of phenothiazines gave rise to the classification of “sedative” versus “incisive” neuroleptics, the former presumably for agitated patients, the latter for the withdrawn and retarded. Yet an analysis by Arthur Platz and coworkers at the Perry Point Veterans Administration Hospital in 1967 demonstrated that there was no difference in therapeutic profiles.

A more important distinction was effectiveness in patients with “positive symptoms” versus those with the apathetic withdrawal of “negative symptoms.” This was realized early. Fritz Freyhan, a German émigré considered one of the founders of psychopharmacology, observed in 1957, at the Second International Congress of Psychiatry in Zurich (the first was in Paris in 1950), “Two schizophrenic patients … may differ fundamentally, one being apathetic, the other excited and disturbed. Only the latter is a candidate for neuroleptic treatment.”

The new drugs marked the beginning of the end of the dominance of psychoanalysis. Heinz Lehmann, who conducted some of the first trials of chlorpromazine, said in a 1992 interview in the Bulletin of the Canadian Psychiatric Association,

> “The demonstration [was important] that psychotropic drugs, such as chlorpromazine … are actually effective, so effective that there remains no doubt even for the sturdiest psychoanalyst. Eventually they had to admit there is a

> physical substrate to schizophrenia and bipolar disorder, because certain physical substances, drugs, definitely are helpful in treating these disorders. (Lehmann H. Psychopharmacotherapy. In: Healy D, ed. *The Psychopharmacologists.* CRC Press; 2001:182.)

It was thus that psychiatry, after so many years out in the cold with psychoanalysis, was able to rejoin the rest of medicine. As Theodore Rothman, at the University of Southern California and Los Angeles Veterans Administration Hospital, said in 1960, at an organizational meeting that would lead to the founding of the American College of Neuropsychopharmacology (ACNP) the following year, "I can find no better keynote thought than that psychopharmacology has given us a common front with the basic medical sciences. Psychopharmacology is compelling us to re-integrate psychiatry into medicine."

Back into medicine! But how did the new drugs work? The 1960s and 1970s were captivated by one-neurotransmitter-one-disease hypotheses.

Norepinephrine was first off the blocks. In 1965, in the American Journal of Psychiatry, Joseph Schildkraut of Harvard University proposed a "catecholamine hypothesis of affective disorders" (the neurotransmitter norepinephrine has a portion with a catechol structure). "Those drugs which cause depletion and inactivation of norepinephrine centrally produce sedation or depression, while drugs which increase or potentiate brain norepinephrine … generally exert an antidepressant effect in man."

In 1968, Swedish pharmacologist Arvid Carlsson and coworkers at Gothenburg University noted in the Journal of Pharmacy and Pharmacology that the TCA imipramine blocked the reuptake of serotonin. "This action may be of importance for its antidepressive properties," the authors said, initiating the serotonin hypothesis of depression.

It remained for dopamine, the third major biogenic amine neurotransmitter, to find its distinctive disease, and this occurred in 1976, as it was reported simultaneously by psychiatrist Solomon Snyder at Johns Hopkins University (in Science) and pharmacologist Philip Seeman at the University of Toronto (in Nature) that the potency of antipsychotic drugs in schizophrenia was a function of their ability to block the dopamine receptor.

The original scientific findings underlying these reports were never overturned, yet neurotransmission is a complex phenomenon, and the field quickly lost confidence in the specificity hypothesis—although, for decades, it was marketed relentlessly by the pharmaceutical industry. In 1978, J.L. Costa and coinvestigators at NIMH said of agents affecting serotonin metabolism, "… It certainly may be that a serotonin deficit state is not a prerequisite for therapeutic efficacy with any of these drugs." It is a shame that these hypotheses, so attractive for their theoretical elegance and simplicity, have now been largely discredited because psychopharmacology has never again been able to develop a unitary theory of drug action. At this writing, the brain remains a black box.

The Golden 50s

The year 1955 saw the launch of the first blockbuster drug in psychiatry, Wallace Laboratories' meprobamate, trade-named Miltown (and Equanil by Wyeth Laboratories, which licensed it from Wallace). Launched as a "tranquilizer," Miltown became almost a household word, opening up that large market for "nerves" between the antipsychotics and aspirin (see below). It was displaced by the benzodiazepines in the 1960s.

The monoamine oxidase inhibitors (MAOIs) were probably the first effective drug class, aside from opium, for serious depression. This awareness took a while dawning. The first MAOI, iproniazid (Hoffmann-La Roche's Marsilid), reached the market in 1951 for tuberculosis, but only in 1957 did the company begin to market it for depression. A series of other MAOIs followed, the most effective of which was probably phenelzine (Warner-Chilcott's Nardil), introduced in 1959 and still in use.

"Tranquilizers"

It was London physician Edward Sutleffe, who had a substantial practice of patients with "nervous irritation" among other diagnoses, who in his *Medical and Surgical Cases* in 1824, introduced into medicine the term "tranquilizer" in connection with a "tranquilizing" drug, "the juice of ground ivy," that he was promoting. The word then slumbered in forgetfulness until 1953, when Ciba billed its new antihypertensive Serpasil (reserpine) as a "safe tranquilizer-antihypertensive." Its calming effects were soon noted in psychological medicine, and the concept of "tranquilization" became the common denominator of a range of drugs from the antipsychotic chlorpromazine, introduced clinically in the United States in 1954, to the "antiphobic" agent benactyzine (Suavitil) that Merck brought out in 1957. The tranquilizers were thought an improvement upon the barbiturates because they had the same relaxing and composing effects without the daytime sedation. Yet soon, the concept of tranquilizer was ruptured by the introduction of the benzodiazepines after 1960 (see below). These "antianxiety" agents made the concept of tranquilization, which had lumped together antipsychotics and antinervous agents, seem outmoded.

Antipsychotics

The antipsychotic era began with the introduction of chlorpromazine in clinical trials in France in 1952 by the Rhône-Poulenc Laboratories. Called Largactil in Europe and Thorazine in the United States, chlorpromazine is thought to have initiated the era of psychopharmacology by prompting research into mechanisms. A slew of similar phenothiazine antipsychotics, also called neuroleptics, followed, including Smith Kline's prochlorperazine (Compazine) in 1956 and thioridazine (Sandoz's Mellaril) in 1958. Haloperidol (Janssen's Haldol, a member of the butyrophenone class) entered practice in the United States in 1966.

Tricyclic Antidepressants

Owing to the close clinical observation of Swiss psychiatrist Roland Kuhn, Geigy Laboratories in Basel realized in 1957 that their new compound imipramine, a member of the tricyclic class, was active against "vital depression," rather than being an antischizophrenic, as they had hoped (the antipsychotic market was just taking off). Marketed in the United States in 1959, imipramine (brand-named Tofranil) initiated a half-century of “antidepressant” treatment. News of the TCAs traveled quickly. At a conference at McGill University in 1959, Hans Hoff, who had become the professor of psychiatry in Vienna after the Second World War, admitted that he and psychoanalyst colleague Paul Schilder “had once tried to destroy the Kraepelinian nomenclature because of the feeling that psychodynamics and personal reactions were more important. Now, however, since a treatment had become available, diagnosis is essential.”

“Mood Stabilizers”

The mood-stabilizer era began with lithium in 1949. The term apparently surfaced for the first time in connection with a drug called aminophenylpyridone (Maltbie Laboratories’ Dornwal) in 1960. The phrase “mood stabilizer” did not, however, come into general use until Robert Post and colleagues at NIMH floated the “kindling hypothesis” in 1986, in the British Journal of Psychiatry: recurrent depressions could tip the brain into autonomous cycles of mood disorder. Other writers then proposed that various anticonvulsants could break into the kindling process and stabilize the hyperirritable brain. Aside from lithium, considered mood stabilizers were: derivatives of valproic acid called valproate and valpromide that medicinal chemist George Carraz at Berthier Laboratories in Grenoble synthesized in 1963; carbamazepine, patented in 1960 by Geigy, was introduced as a psychoactive compound in Japan, then discovered in 1980, by NIMH investigators to have effects in manic-depression. Lamotrigine was patented by the Wellcome Foundation in 1981 and inaugurated in 2003 in the United States by GlaxoSmithKline as Lamictal (“a stabilizing force”). The judgment of David Healy and colleagues in 2003, in Bipolar Disorders, was that “These agents are now thought of as being a homogeneous group [but] they may, in fact, be quite diverse agents all of which have a certain utility when used judiciously in manic depressive states.”

After the 1950s, Relatively Few New Drug Classes

Benzodiazepines. The benzodiazepine story began with the marketing of Hoffmann-La Roche's Librium (chlordiazepoxide) in 1960. The numerous subsequent Roche benzos were also synthesized by medicinal chemist Leo Sternbach. So popular did the benzodiazepines become that entire "eras" in the 1960s and 1970s were named after such members of this class as Valium (diazepam, launched in 1963). With the exception of the SSRIs (selective serotonin reuptake inhibitors—see below), the benzodiazepines are probably the best-selling psychoactive drug class in history and moreover possessed genuine efficacy that later agents do not seem to have matched. Other benzos followed: clonazepam (Klonopin) reached the American market in 1975, and alprazolam (Upjohn's Xanax) was launched in 1981. A short-acting benzo, Upjohn's triazolam (Halcion), came out in the United States in 1982 and caused much controversy about discontinuation. There was a long period of fearfulness about addiction, although in 1983, in the Journal of the American Medical Association, Karl Rickels and associates at the University of Pennsylvania found the risks of withdrawal reactions in diazepam minimal for up to 8 months of use. In the new millennium, the benzos began a comeback. As Peter Roy-Byrne at the University of Washington School of Medicine put it in an editorial in 2014 in the American Journal of Psychiatry, "There is now general appreciation that, with careful clinical evaluation to rule out pre-existing addiction issues … benzodiazepines are safe and highly effective."

Selective Serotonin Reuptake Inhibitors (SSRIs). Marketed as agents that specifically inhibited the neuronal reuptake of serotonin, this drug class became the most successful in the history of psychiatry. Prozac (fluoxetine), which became a household word, was marketed by the Eli Lilly Company in Belgium in 1986, in the United States in 1988. Among the main SSRIs, there followed Pfizer's Zoloft (sertraline), marketed in 1992; paroxetine (Novartis's Paxil), introduced in the United States in 1993; and citalopram

(Lundbeck’s Cipramil), brought out in the United States in 1998 by Forest Laboratories (Celexa). The SSRIs were initially indicated for “depression,” then for “anxiety,” and by the time they all finally went off patent, countless were the indications for which this versatile drug class served.

Second-Generation Antipsychotics. The so-called “second-generation antipsychotics” (SGAs) have turned out not that different from the first generation and seem to be more a marketing concept. Yet, it might be noted that clozapine (Sandoz’s Clozaril), deemed the most effective of them, is not exactly a new drug, having been patented in 1963. Leo Hollister’s judgment in 1987 of the antipsychotics is of interest (Hollister led the Veterans Administration hospital in Palo Alto, California and is generally acknowledged as the dean of American psychopharmacology): “It is most discouraging that more effective pharmacotherapy for schizophrenia has not been developed in the more than three decades since the introduction of the first effective drugs.” The current drugs, he said,

> are not curative; their ameliorative effects are often limited; many patients remain totally unresponsive; they are unpleasant to take, so that many patients are less than fully compliant; and they produce major side effects.

PEDIATRIC PSYCHIATRY

Psychiatrists have always been familiar with mental diseases in children. In 1809, Haslam reported cases of “insane children,” such as a 7-year-old boy who was slow to develop and was placed on “the female side” of the hospital. Early on, psychotic illness in children was noted, sometimes as a distinctive form of what would later be called childhood schizophrenia, sometimes not. The “hebephrenia” that Ewald Hecker described in 1871 was commonly recognized in children. As Auguste Voisin, a staff psychiatrist at the Salpêtrière in Paris, commented in his 1883 textbook of “insanity in the young”: “In partial insanity, the child may be manic [extatique], subject to ideas of homicide, arson, or theft, have deluded and demonic ideas … It is in the context of this partial insanity that we find the singular cases of childhood suicide, sometimes preceded by notes from which extreme exaltation shows through; thus a child of thirteen who hanged himself left behind a note saying, ‘I bequeath my soul to Rousseau, my body to the earth.’”

Textbooks of child psychiatry were not slow in coming. In 1887, Hermann Emminghaus, professor of psychiatry in Freiburg, produced what was probably the first, *The Psychic Disorders of Childhood* (*Die psychischen Störungen des Kindesalters*). The foundational modern text of psychological approaches to disorders of childhood, *Lectures on the Psychopathology of Childhood* (*Vorlesungen über Psychopathologie des Kindesalters),* was written by August Homburger at the Heidelberg University Psychiatric Hospital in 1926. Among the first dedicated hospital divisions for children with mental illnesses was that at Bicêtre Hospice in Paris, which in 1838, received responsibility for the care of “children with mental retardation and epilepsy.” In 1842, Édouard Séguin, who had developed a system for the care of children with retardation, took over the service, and after an interregnum, in 1851, Louis Delasiauve succeeded him. Désiré-Magloire Bourneville took it over in 1879, and in the course of the next decades, made Bicêtre into one of the most progressive children’s psychiatric units in the world. (In 1892, he initiated a gymnastic competition, which became the unacknowledged forerunner of the Special Olympics.) In 1850, Séguin emigrated to the United States and initiated here the enlightened treatment of children who have what are now called intellectual disabilities.

The epidemic of encephalitis lethargica in the years 1917 to 1927 represented a strong inflection in the growing awareness of distinctive psychiatric illness in children, primarily because, unlike adults, the disease produced striking psychiatric changes in many children, transforming them from normal happy creatures into the “apache type” with severe behavioral problems. Said Leslie Colin Cook, who was a staffer at the West Park Mental Hospital in Epsom that had a center for such patients, in the Lancet in 1928, “Children of irreproachable family, hitherto of exemplary behavior and character, may in a very short period become guilty of every delinquency from mere naughtiness to cruelty and murder, and from mild bad habits to gross indecencies." This had happened, he said, in only one adult patient with the disease. The "EL" epidemic thus strengthened the interest of the field in children as a special kind of patient.

In the middle third of the 20th century, psychoanalysis became the doctrinal mainstay of child psychiatry. Freud himself did not see children and had relatively little experience with them. Psychoanalysis was first applied to the child, and adolescent population by Viennese educator and psychoanalyst August Aichhorn in his 1925 work Wayward Youth (Verwahrloste Jugend), about the ego structure of juvenile delinquency. Sigmund Freud's daughter Anna published her first book in 1927, An Introduction to the Technique of Child Analysis, and in 1936, The Ego and the Mechanisms of Defense. The Freud family fled to England after the Nazi Anschluss with Austria in 1938, and in 1941, Anna Freud helped found the Hampstead Nursery in London, where she treated children for several years. This gave way to the Hampstead Child Therapy Course and Clinic, which Anna directed until her death in 1982 (on her rivalry with Melanie Klein see above).

After the Second World War, the baton in child psychiatry passed to the United States. When the National Institute of Mental Health opened in 1949, the "quality of mothering" was put on the table—especially so by psychoanalysts such as Frieda Fromm-Reichmann at Chestnut Lodge in Maryland, who, in Psychiatry in 1948, had originated such concepts as the "schizophrenogenic mother." Among the leading child psychoanalysts in New York was Hungarian-born Margaret Mahler, who in 1950 cofounded the Masters Children's Center in Manhattan, where she developed the tripartite treatment model involving the mother in the child's treatment. Her most important work was *The Psychological Birth of the Human Infant* (1975).

Prompted by an interest in the ideas of Harvard psychologist Burrhus Frederick Skinner, in the late 1940s and 1950s, behaviorism started to become à la page. Psychoanalysis and behaviorism dominated pediatric psychiatry in the United States after the Second World War.

The child guidance clinics reached back to the First World War, and in 1948 they created an organization of clinics, the American Association of Psychiatric Clinics for Children, to develop standards of care and training. In 1953, the American Academy of Child Psychiatry was founded; in 1959, the American Board of Psychiatry and Neurology approved a 2-year child psychiatry residency to be grafted onto the regular training. The field received its own voice, The Journal of the American Academy of Child Psychiatry, in 1962, and a quarter-century later, in 1986, the Academy changed its name to the American Academy of Child and Adolescent Psychiatry.

In the heyday of psychoanalysis, “pills” were frowned on and great confidence placed in psychotherapy. Yet, the revolution in adult psychopharmacology in the 1950s had echoes in the pediatric world. “Psychopharmacology has revolutionized child psychiatry,” said Jovan Simeon, professor of psychiatry and child psychopharmacologist at the University of Ottawa, in 2004. Children had, of course, always been treated with such psychoactive agents as opium, mixed together with alcohol in laudanum (see above), which parents once routinely administered as a hypnotic. Treating children with psychopharmaceuticals entered the academic forum in 1937, when Charles Bradley, director of the Emma Pendleton Bradley Home in East Providence, Rhode Island, in the American Journal of Psychiatry reported the benefit of Benzedrine in “behavior problem” children, later defined as “hyperactive.” Loretta Bender, at Bellevue Hospital in New York, used chlorpromazine and amphetamine extensively in treatment. Systematic research in pediatric psychopharmacology began in 1958 when Leon Eisenberg at Johns Hopkins University received the first NIMH grant to study drugs in children, conducting the first controlled trial in pediatric psychopharmacology. This torch was then notably carried forward by Bender’s student Barbara Fish, first at Bellevue, then after 1972, at UCLA.

Such progress in pediatric psychopharmacology probably counts as an American “first.” There were a number of other American firsts, such as recognition by Lee Wachtel at the Kennedy Krieger Institute in Baltimore and Dirk Dhossche, in a 2010 article in Medical Hypotheses, of stereotypical movements in autism and intellectual disability as a sign of catatonia—and treatable with benzodiazepines and convulsive therapy.

As for diagnosis, disease classification in pediatric psychiatry has been in even greater turmoil than in general psychiatry, as psychoanalysis, behaviorism, and biologic approaches have dueled. Driven by parental concerns, clinicians are often pressed to make diagnoses such as ADHD. The fourth edition of DSM (DSM-IV) included the diagnosis "bipolar II disorder," characterized by depression plus "at least one hypomanic episode." Yet the field readily accepted outbursts of anger as a substitute for hypomania, touching off a virtual epidemic of "bipolar II" in the pediatric population, which the embarrassed drafters of DSM-5 were obliged to dial back in 2013, with the newly contrived "depressive" diagnosis "disruptive mood dysregulation disorder," said to be "included for children up to age 18 years who exhibit persistent irritability and frequent episodes of extreme behavioral dyscontrol." The classification of illness in children has thus still not stabilized.

NEW FORMS OF CARE

The asylum was a forbidding institution. Yet many patients outside its walls also required care, and over the years, these walls were slowly broken down.

Boarding patients out to local families achieved first this separation of care from the four walls of the institution. The earliest instance of this was seen at Gheel in the Brabant region of Belgium, where patient out-boarding went back to the 13th century. Yet the local farmers often had little tolerance for the antics of the patients, of whom they might board up to five at a time, and when Pliny Earle, of the Friends' Asylum in Frankford, visited there in the late 1830s (describing his travels in a book in 1841, he was shocked to find that the patients, "if mischievous or furious, are chained at the wrists and ankles. In every house, there is a ring beside the chimney, or attached to the beds, to which they may be chained." Boarding out was never widespread in the United States, possibly because the farms were too dispersed (unlike the compact Belgian villages). But in Scotland, around 1900, 23% of the asylum patients were boarded out.

There were other ways of breaking down the walls. The first psychiatric ward in a general hospital in the United States was established in 1902 at Albany Hospital. In 1885, Pennsylvania Hospital founded the first outpatient clinic, or very close to the first, in the United States, "so as to provide a dispensary service for the gratuitous treatment of persons suffering with incipient mental disease." (On these developments, see Henry Hurd's massive four-volume work in 1916 on the Institutional Care of the Insane.)

One of the unhappiest stories in U.S. psychiatry was that of "deinstitutionalization," under the influence of the antipsychiatric ideologies of the 1960s, discharging in-patients to a kind of community care that often turned out to be the care of the streets. This created an existential dilemma for psychiatry: what to do with the patients who were seriously ill? As Jonathan Cole said in an interview in 1996,

> We've got few places where we can serve the kind of patient who takes a long time to get better and where real rehabilitation is done. We tend to have more people who are home and crazy than we should have and nobody's going to pay for their treatment.

Beginning in the 1960s, this vast outpouring resulted in the closing of many of the classic asylums. In 1964, there were in the United States 255 public psychiatry beds per 100,000 population; by 2014, this figure had dropped to 11 per 100,000. The patients were supposed to be maintained in community settings on antipsychotics; in reality, they fed the vast ranks of the "homeless" and the imprisoned. In 2002, 64.2% of all inmates of local jails in the United States had a "mental health problem" (75.4% of the females). The figures were comparable for state and federal prisons. Donald Klein of Columbia University said later in an interview,

> "It wasn't deinstitutionalization, it was trans-institutionalization. The patients, but not the money, were dumped on the cities. There was a sudden rise in homelessness. This led to federally supported 'community care,' staffed by therapy-minded psychologists. They had a psychiatrist who did little but sign bundles of prescriptions.

By one estimate, "There are 10 times as many mentally ill persons in prisons than in state hospital beds." David Rubinow at the UNC, who penned these lines in the American Journal of Psychiatry in 2014, concluded,

> It would appear that we somehow have achieved the complete reversal of policies initiated over 170 years ago to ensure the humane treatment of those with mental illness.

Yet history has good news as well. On the threshold of the new millennium, the role of psychiatry itself was slowly changing. Once seen as a band-aid for the "walking wounded," psychiatry was becoming the main resource for the seriously ill. In the United States from 2001 to 2002, 40% of patients identified in a national household survey with a serious mental problem would be seen by a psychiatrist. As for the rest of patients who formerly would have been "in therapy," psychiatry had ceased to be the main port of call: only 21% of those with moderate and 9% of those with mild disorders saw psychiatrists; they distributed themselves instead across the entire gamut of mental and medical health services, from "general medical" to "internet" (the main resource for 30% of those with "moderate" mental problems). Alarmingly, of those seeing a psychiatrist, 29% were said to have "no disorder." Readers will give a weary sigh. Yes, it's true: some things never change.

World Aspects of Psychiatry

SAM GNANAPRAGASAM, B.SC., M.B.B.S., M.R.C.PSYCH., MAX PEMBERTON, M.B.B.S., B.SC., M.R.C.PSYCH., PEDRO RUIZ, M.D., ANTONIO VENTRIGLIO, M.D., PH.D., AND DINESH BHUGRA, C.B.E., M.A., M.SC., M.B.B.S., F.R.C.P., F.R.C.P.E., F.R.C.PSYCH., F.F.P.H., M.PHIL., PH.D., F.R.C.PSYCH. (HON), F.H.K.C.PSYCH. (HON), F.A.C.P. (HON), F.A.M.S. (SINGAPORE), F.I.M.S.A. (HON)

Mental health disorders are highly prevalent across all regions of the world. These disorders represent a major source of disability and social burden. Even though treatments for these disorders are known and have been found to be efficacious in both high-, middle-, and low-income countries, this has not always translated into wider access, availability, and affordability of these interventions. Mental disorders remain undertreated worldwide, even when accounting for variation across societies and cultures. A treatment gap of more than 90% has been documented in some low-income countries, but even in high-income countries, high levels of gap remain. To complicate matters further, many countries do not have any mental health policies, and there are many others that have outdated policies originating in the 19th century. Consequently, both funding for treatment and research into mental health falls well below what is required or what is offered for physical disorders such as cancer and heart disease.

In recent years, there has been a focus on mental health provision around the world. This has led to the emergence of the global mental movement. Partly this is a response to rapid globalization, which has meant that people, resources, and ideas are moving much more rapidly than at any other time in the history of humanity. This has led to a clear acknowledgment that a number of factors at social and cultural levels are at play in influencing how distress is experienced and expressed. The thinking behind this movement is outlined in seminal literature such as the 2007 and 2011 Lancet Series on Global Mental Health and later revised 2018 Lancet Commission on Global Mental Health and Sustainable Development.

There remains a danger in that global mental health may follow the route of Anglo-American influences to be seen “dictating” to the low- and middle-income countries. Reassuringly, the latest commission report has reframed mental health within the Sustainable Development Goals framework and sought to establish mental health as a pillar of universal coverage. It has also sought to advocate for the use of public policies to protect mental health, including through investment and research innovation, as well as engagement with people with lived experience and strengthening of monitoring and accountability.

The international progress of collaboration has shifted considerably over the past two centuries. Initially, the rulers saw the vanquished as exotic natives who either did not have the mental capabilities to develop mental illness or, later, saw them as victims of biologic, social, and geopolitical factors. This gave way to international collaborative epidemiologic studies, which have contributed to the current understanding of both similarities and differences in etiology and outcomes of psychiatric disorders.

Although there have been many proclamations internationally recently about the importance of mental health, resources to deal with mental disorders and investing in public mental health have not followed the rhetoric. The contribution of funding to mental health care remains scarce and unequally distributed.

The authors prefer and choose the term “world psychiatry” in this chapter, as it reflects the real state of psychiatry at the present time. This chapter provides an overview of world psychiatry but focuses on epidemiology, the burden resulting from mental illness, the relationship between various illnesses, stigma, and the ethics of mental health care. There remain several serious questions in relation to the differences in rates and responses across different nations of the world. Some of these are discussed later in this chapter.

PREVALENCE AND BURDEN OF MENTAL DISORDERS WORLDWIDE

World Health Organization (WHO) estimates that more than one in four individuals worldwide develop one or more mental disorders during their lifetime. The Global Burden of Disease (GBD) project and studies that were undertaken provide specific data on multiple diseases from around the world. Herein Table 60–1, we report mental health prevalence findings from the 2017 study.

These findings in Table 60–1 are supported by a series of face-to-face community surveys conducted in 17 countries in Africa, Asia, the Americas, Europe, and the Middle East. These World Mental Health Surveys have included a total of 85,052 respondents. The lifetime prevalence of any mental disorder was found to be higher than 25% in 11 of 17 countries and higher than 15% in all countries except China and Nigeria, where prevalence rates were likely to be downwardly biased due to respondent reluctance to admit mental health problems. Whether these rates are genuinely low or whether these reflect reporting bias needs further exploration.

Not surprisingly, anxiety disorders were the most prevalent in 10 out of 17 countries, and mood disorders in 6 (Table 60–2). Anxiety disorders include agoraphobia, adult separation anxiety disorder, generalized anxiety disorder, panic disorder, posttraumatic stress disorder, social phobia, and specific phobia. Mood disorders include bipolar disorders, dysthymia, and major depressive disorder. Impulse-control disorders include intermittent explosive disorder and reported persistence in the past 12 months of symptoms of three child–adolescent disorders (attention-deficit/hyperactivity disorder, conduct disorder, and oppositional-defiant disorder). Substance disorders include alcohol or drug abuse with or without dependence. Following the *Diagnostic and Statistical Manual of Mental Health Disorders*, Fourth Edition (DSM-IV) norms, organic exclusions were excluded.

Lifetime co-occurrence of two or more mental disorders was quite common, so the sum of the prevalence rates across the various disorder types was between 30% and 50% higher than the proportion of people having at least one mental disorder. Survival analysis showed that the odds ratios for anxiety, mood, and substance use disorders were higher in recent compared to older cohorts. It is worth noting that even within the same geographical region, there appear to be major variations in the prevalence of DSM-IV/CIDI disorders.

Table 60–1.

Mental Health Disorder Prevalence from Global Burden of Disease 2017 Study

Disorder	Share of Global Population with Disorder (2017) [difference across countries]	Number of People with the Disorder (2017)	Share of Males: Females with Disorder (2017)
Any mental health disorder	10.7%	792 million	9.3% males 11.9% females
Depression	3.4% [2–6%]	264 million	2.7% males 4.1% females
Anxiety disorders	3.8% [2.5–7%]	284 million	2.8% males 4.7% females
Bipolar disorder	0.6% [0.3–1.2%]	46 million	0.55% males 0.65% females
Eating disorders(clinical anorexia & bulimia)	0.2% [0.1–1%]	16 million	0.13% males 0.29% females
Schizophrenia	0.3% [0.2–0.4%]	20 million	0.26% males 0.25% females
Any mental or substance use disorder	13% [11–18%]	970 million	12.6% males 13.3% females
Alcohol use disorder	1.4% [0.5–5%]	107 million	2% males 0.8% females

Drug use disorder (excluding alcohol)	0.9% [0.4–3.5%]	71 million	1.3% males 0.6% females

[a] Anxiety disorders include agoraphobia, adult separation anxiety disorder, generalized anxiety disorder, panic disorder, posttraumatic stress disorder, social phobia, and specific phobia. Mood disorders include bipolar disorders, dysthymia, and major depressive disorder. Impulse-control disorders include intermittent explosive disorder, and reported persistence in the past 12 months of symptoms of three child–adolescent disorders (attention-deficit/hyperactivity disorder, conduct disorder, and oppositional-defiant disorder). Substance disorders include alcohol or drug abuse with or without dependence. In the case of substance dependence, respondents who met full criteria at some time in their life and who continue to have any symptoms are considered to have 12-month dependence even if they currently do not meet the full criteria for the disorder. Organic exclusions were made as specified in the *Diagnostic and Statistical Manual of Mental Health Disorders (DSM)*, 4th edition.

[b] Impulse disorders are restricted to age ≤39 (China, Ukraine, Nigeria) or to age ≤44 (all other countries).

[c] Adult separation anxiety disorder was not assessed.

[d] Specific phobia was not assessed.

[e] Bipolar disorders were not assessed.

[f] Intermittent explosive disorder was not assessed.

[g] Attention-deficit/hyperactivity disorder was not assessed.

[h] Conduct disorder was not assessed.

[i] Oppositional-defiant disorder was not assessed.

[j] Only alcohol abuse with or without dependence was assessed. No assessment was made of other drug abuse with or without dependence.

[k] People's Republic of China.

Reproduced with permission from Kessler RC, Aguilar-Gaxiola S, Alonso J, et al. The global burden of mental disorders: an update from the WHO World Mental Health (WMH) surveys. *Epidemiol Psichiatr Soc*. 2009;18(1):23–33. doi:10.1017/s1121189x00001421.

In the same series of studies, the 12-month prevalence showed similar variations. These findings illustrated regional and national variations. Once again, Nigerian respondents reported only 6% prevalence, with similar figures from Japan and China, but the rates were 4.5 times higher in the United States (see Table 60–3).

As shown in Table 60–4, when the association between 12-month severity and days out of role were compared, again, variations within regions and across nations were substantial. Once again, Nigeria and China had similar figures, whereas the United States showed the highest levels.

When the severity of these disorders was compared across nations and regions, similar variations emerged. China, Japan, Nigeria, and this time Italy showed lower levels of serious severity and higher levels of mild severity (see Table 60–5).

Using the disability scale for common chronic physical and mental health disorders, interesting differences emerged between developed and developing countries (see Table 60–6). Cancer, asthma, hypertension, and diabetes showed higher proportions of severe disability in developing countries, whereas neck and backaches, chronic pain, and headaches were more seriously disabling in developed countries. Bipolar disorders, depression, generalized anxiety disorders, panic disorders, and posttraumatic disorder–related disability was elevated in developed countries. This variation raises interesting questions about whether these are genuinely higher levels or are rather more commonly diagnosed.

Primary Care

Among people seen by primary health care professionals, more than 20% have one or more current mental disorders. In a study carried out by the WHO at 14 sites in Africa, Asia, the Americas, and Europe, the average current prevalence of any mental disorder was 24%, without consistent differences between low- and high-income countries. Not surprisingly, the most common diagnoses were those of depression (average 10.4%) and generalized anxiety disorder (average 7.9%). Female rates were 1.89 times higher than male rates for depression, but male rates were higher for alcohol-related disorders, so there was no sex difference in the proportion of people having at least one mental disorder. Physical ill-health and educational disadvantage were both significantly associated with a diagnosis of mental disorder.

Disability-Adjusted Life Years (DALYs)

In addition to measures of prevalence, understanding the impact of mental health globally must also take into account the morbidity associated with disabling mental health conditions. To quantify the burden of various diseases and injuries, the WHO, in collaboration with the Harvard School of Public Health and the World Bank, introduced in 1993 a new measure, the disability-adjusted life year (DALY). DALYs for a given disease or injury are the sum of the years of life lost due to premature mortality plus the years lost due to disability for incident cases of that disease or injury in the general population.

[a] No demographic controls were used.

[b] Significant association between severity and days out of role at the 0.05 level.

Reproduced with permission from Kessler RC, Aguilar-Gaxiola S, Alonso J, et al. The global burden of mental disorders: an update from the WHO World Mental Health (WMH) surveys. *Epidemiol Psichiatr Soc*. 2009;18(1):23–33. doi:10.1017/s1121189x00001421.

In the original estimates for the year 1990, mental and neurologic disorders accounted for 10.5% of the total DALYs lost due to all diseases and injuries. The burden of disease related to mental health disorders and related temporal change from 1990 to 2017 is shown by way of years lived with a disability (YLDs) in Table 60–7. When a comparison is made between years lived with disability due to depression between 2007 and 2017, it appears that the years have increased by 12.6% due to major depressive disorders and dysthymia by over 20%.

The WHO estimates that one in four families worldwide has at least one member suffering from a mental disorder. The objective and subjective burden related to caring for people with severe mental disorders (in terms of disruption of family relationships; constraints in social, leisure, and work activities; financial difficulties; negative effect on physical health; feelings of loss, depression, and embarrassment in social situations; and the stress of coping with disturbing behaviors) have been reported to be substantial and significantly higher than that related to caring for people with long-term physical diseases such as diabetes, heart, kidney, or lung diseases. Cross-cultural differences have been reported in some dimensions of family burden: for example, relatives in the Mediterranean area compared with those in northern European countries were found to be more resigned and to use spiritual help more frequently as a coping strategy. They reported a greater level of reduction in social interests and lower levels of support from their social network.

Children and Adolescents

The mental health and well-being of young people are important to consider, given they represent a substantial proportion of the world's residents, with one in six people aged between 10 and 19. More than half of all mental health conditions are thought to start by the age of 14. However, most are not diagnosed or treated. The consequences of not treating mental health conditions during this period have profound ramifications as the impact extends into adulthood and limits functional abilities.

The prevalence of mental disorders among children and adolescents is difficult to evaluate because it is problematic to draw a reliable boundary between psychopathological phenomena and some manifestations that are part of normal development. Population surveys may help, but access to schools and clinics is extremely variable. Hence the accuracy of figures can be challenged. Many studies have used checklists compiled by parents and teachers, which are useful in detecting cases needing special attention but may not represent an appropriate basis for prevalence estimates.

Ten percent of all children and adolescents are thought to experience a mental disorder. In adolescents (aged 10 to 19), mental health conditions are thought to account for 16% of the GBD in that group. A GBD study among children between the ages of 5 and 14 found that mental disorders were among the leading causes of both DALYs in Europe, North America, and South America. They were in the top five causes in South East Asia, the Eastern Mediterranean, and the Western Pacific. Infectious diseases held a greater burden in Africa, and as such, mental health disorders were not among the top five causes of DALYs. It is likely that as low- and middle-income countries undergo epidemiologic transitions away from communicable disease, the share of disease burden related to mental health disorders will increase among young people.

Suicide

According to WHO estimates, around 703,000 people died from suicide worldwide in the year 2019. This accounted for 1.3% of total deaths that year. The global age-standardized suicide rate was 9 per 100,000. Notably, there is a wide range between countries—less than 2 to over 80.0 deaths per 100,000. Globally, the age-standardized mortality rate was higher among men (12.6 per 100,000) compared to women (5.4 per 100,000). The suicide rate, therefore, was 2.3 times in men compared to women—was notably over 3 in high-income countries, 2.8 in upper-middle–income countries, 1.8 in upper-middle–income countries, and 2.9 in low-income countries. By and large, younger people and older adults had higher rates than middle-aged adults.

Around 77% of the suicides in 2019 occurred in low-and-middle-income countries. While this was the case and related to large overall populations, high-income countries had a higher age-standardized rate (10.9 per 100,000) compared to upper-middle–income countries (7.3 per 100,000), lower-middle–income countries (10.1 per 100,000) and low-income countries (9.9 per 100,000). Suicide rates varied by region (global average of 9.0 per 100,000): Europe, Africa, and South East Asia had higher rates at 10.5, 11.2, and 10.2 per 100,000, respectively. The Eastern Mediterranean region had the lowest rate at 6.4 per 100,000. In adolescents, the number who died by suicide in those countries is greater at 88%. Among young people aged between 15 and 29, suicide was the fourth leading cause of death.

*Percentage changes that are statistically significant.

Adapted from GBD 2017 Disease and Injury Incidence and Prevalence Collaborators. Global, regional, and national incidence, prevalence, and years lived with disability for 354 diseases and injuries for 195 countries and territories, 1990–2017: a systematic analysis for the Global Burden of Disease Study 2017. *Lancet.* 2018;392(10159):1789--1858. doi: 10.1016/S0140-6736(18)32279-7. https://creativecommons.org/licenses/by/4.0/

The age-standardized mortality rate decreased by 36% between 2000 and 2019. The rate decreased most, by 49%, in the Western Pacific Region. Although the overall decrease between 1990 and 2019 is promising and substantial, if the current trajectory continues, most countries will not meet the Sustainable Development Goals target of reducing suicide-related mortality by a third from 2015 to 2030.

Globally, the trends and varied patterns of suicidality reflect an interplay of different factors. These include socio-cultural, religious, and sociodemographic inter- and intra-country differences. In addition, economic circumstances, unemployment, exposure to violence, use of alcohol and drugs, patterns of mental disorder, and access to means of suicide (e.g., access to firearms) were all found to play a key role.

TREATMENT GAP AND PROJECTED POPULATION-LEVEL TREATMENT EFFECTIVENESS WORLDWIDE

Lifetime contact for treatment delay in various psychiatric conditions is shown in Table 60–8. Interestingly, common mental disorders showed longer delays. This is further confirmed in the 12-month service use by sectors (see Table 60–9).

The efficacy of pharmacologic and psychosocial treatments for mood, anxiety, psychotic, and substance-related disorders has been convincingly proved by clinical trials carried out in low- and middle-income as well as in high-income countries. However, the treatment gap is substantial for all mental disorders worldwide, in particular, in low-income countries.

In the World Mental Health Surveys, carried out in representative community samples in 17 countries in Africa, the Americas, Asia, Europe, and the Middle East, the proportion of lifetime cases of anxiety disorders making treatment contact in the year of disorder onset ranged from 0.8% in Nigeria to 36.4% in Israel. The proportion of cases making treatment contact by 50 years ranged from 15.2% in Nigeria to 95.0% in Germany. The median delay to treatment among cases eventually making contact ranged from 3 years in Israel to 30 years in Mexico (Table 60–10).

For Schizophrenia, a systematic review by Jääskeläinen and colleagues that was based upon 50 studies looking at outcomes found that only 13.5% of people with Schizophrenia (median) met clinical and social recovery criteria.

The proportion of lifetime cases of mood disorders making treatment contact in the year of disorder onset ranged from 6% in Nigeria and China to 52.1% in the Netherlands. The proportion of cases making treatment contact by 50 years ranged from 7.9% in China to 98.6% in France. The median delay to treatment among cases eventually making contact ranged from 1 year in Belgium, The Netherlands, Spain, and Japan to 14 years in Mexico (Table 60–11).

The proportion of lifetime cases of substance use disorders making treatment contact in the year of disorder onset ranged from 0.9% in Mexico to 18.6% in Spain. The proportion of cases making treatment contact by 50 years ranged from 19.8% in Nigeria to 86.1% in Germany. The median delay to treatment among cases eventually making contact ranged from 6 years in Spain to 18 years in Belgium (Table 60–12).

Table 60–8.

[a] Number of participants is unweighted, but percentages, means, and medians are weighted.

[b] Treatment delay is expressed as years between disorder onset and initial treatment contact. Delay was set at zero years for persons with initial treatment contact before disorder onset or in the year of disorder onset.

[c] Measured for respondents aged 18–44 only.

Reprinted with permission from Wang PS, Angermeyer M, Borges G, et al. Delay and failure in treatment seeking after first onset of mental disorders in the World Health Organization's World Mental Health Survey Initiative. *World Psychiatry*. 2007;6(3):177–185.

In the World Mental Health Surveys, failure and delays in treatment-seeking were generally greater in low-income countries, older cohorts, men, and cases with earlier ages of onset. The earlier treatment contact of people with mood disorders might be partly due to the fact that these disorders have been targeted by educational campaigns and primary care quality improvement programs in several countries.

The Disease Control Priorities Project Report estimated the cost of a mental health care package consisting of outpatient treatment of schizophrenia and bipolar disorder with first-generation antipsychotics or mood stabilizers and adjuvant psychosocial interventions and treatment of depression and panic disorder in primary care with generic selective serotonin reuptake inhibitors. The cost per capita of the package was projected to be US$ 3 to 4 in sub-Saharan Africa and South Asia and US$ 7 to 9 in Latin America and the Caribbean. The addition of brief interventions by primary care physicians for high-risk alcohol users was projected to cost a further US$ 0.04 per capita in sub-Saharan Africa and South Asia and up to US$ 0.36 per capita in Central Asia and Latin America. Treatment of common mental disorders was reported to be in the same range of cost-effectiveness as antiretroviral treatment for HIV/AIDS, secondary prevention of hypertension, or glycemic control for diabetes.

RESOURCES FOR MENTAL HEALTH CARE WORLDWIDE

According to the Mental Health Atlas 2017, 79% of the 139 countries that responded had a standalone mental health policy or plan (i.e., a document of the government or ministry of health specifying the goals for improving the mental health situation of the country, the priorities among those goals, and the main directions for attaining them). This ranged from 72% in the African region to 90% in the South East Asia region (see Table 60–13). This is a notable improvement from findings in the Mental Health Atlas 2005, whereby Africa and Southeast Asia regions had 50% and 54.5%, respectively, of countries in their regions with mental health policy. Despite improvement, there remains a difference in the existence of policy and plans, and this reflects a number of factors. This could be attributed to the low importance of mental health in many countries and settings. It also has been explained on the basis of colonial rule, where the laws have not changed even after independence. 22 of the 36 countries that stated that they did not have standalone policies or plans for mental health had others have integrated policies for mental health as part of general health or disability policies. With regard to children and adolescent mental health, of the 78 countries that responded, only 46% had a plan or strategy.

Even where mental health plans are present, they have often not been supported by sufficient human and financial resources. Less than half of the countries surveyed had policies and plans that aligned with human rights conventions related to the participation of service users in decisions concerning them and stressed the importance of the transition from inpatient to community-based care. Specifically related to suicide, only a few countries had prevention strategies—approximately a third of high-income and upper-middle–income countries and 10% of low- and middle-income countries.

The Mental Health Atlas also considered the number of countries with mental health legislation and found that only 63% of countries (111 of 175 surveyed) had one. This varied from 44% in the African region to 77% in the European region (Table 60–14). Further, in some regions such as Africa and South East Asia, most countries did not have a dedicated authority or independent body to ensure compliance of mental health legislation with international human rights principles (Table 60–15).

The median number of adult psychiatric beds per 100,000 population ranges from 2.5 in the African region to 59.7 in the European region (see Table 60–16). When considering availability related to the income status of countries, high-income countries had 52.6 beds per 100,000 compared to 1.9 beds per 100,000 in low-income countries. This significant disparity is ongoing despite the transition toward community-based residential care in high-income settings. Community care provision continues to lag in some regions, with a median rate of 437 visits per 100,000 in the South East Asia region compared to 8,073 in the European region (see Table 60–17) significantly. When considering rates related to income status of countries, high-income countries have 36 times the rate of adult outpatient visits compared to low-income countries (7,966 vs. 000220 per 100,000).

The global median mental health expenditure per capita in 2017 was 2.5 USD. Of the overall governmental health expenditure pie, mental health was less than 2% of the global median. There was noted to be significant variation between regions, with the European region spending 20 times that of the South East Asian and African regions. Notably, most of the mental health budget (approximately 80%) in low- and middle-income countries is spent in inpatient mental health hospitals. On the other hand, high-income countries spent approximately 43% on inpatient mental health hospitals.

Out-of-pocket payment is the most important method of financing mental health care in 43% of countries in Africa and 40% of countries in Southeast Asia, whereas it is not the primary method of financing mental health care in any European country (Table 60–18). Further, national health insurance and other reimbursement schemes did not cover care and treatment of severe mental disorders in two-thirds of countries globally.

Southeast Asia	1.21	437
Western Pacific	2.08	693

Modified from World Health Organization. *Mental Health Atlas 2017*. World Health Organization; 2018.

The global median of health workers is 9 per 100,000. The median number of psychiatrists per 100,000 population ranges from 0.4 in South East Asia to 9.9 in Europe (Table 60–19). The median number of psychiatric nurses per 100,000 population ranges from 0.5 in Africa to 23.2 in Europe. The median number of psychologists working in mental health care per 100,000 population ranges from 0.1 in Southeast Asia and Africa to 5.4 in the Americas.

Nurses represent the single largest category of mental health workers, with between 30% and 50% of the overall workforce in the different regions. Notably, in the African and American regions, the number of psychiatrists and psychologists is greater than the number of nurses (see Table 60–19). Large-scale migration of psychiatrists and other mental health professionals from low- and middle-income to high-income countries, as part of the larger picture of migration of health professionals in general, has been consistently documented. India and some sub-Saharan African countries are the most important contributors to the mental health workforce in the United Kingdom, although the United Kingdom has higher rates of psychiatrists per million population compared to India and sub-Saharan African countries.

Even worse is the situation concerning child and adolescent mental health care. According to the Mental Health Atlas, only 46% of countries worldwide have a specific child and adolescent mental health policy. With regard to inpatient bed availability for this population, high-income countries have eight times the number of beds as low-income countries. In terms of outpatient care, there is a similarly striking discrepancy. The median in child and adolescent outpatient visits was 1,609 per 100,000 in high-income countries and 11 per 100,000 in low-income countries. With regard to workforce availability, there are less than 0.1 psychiatrists per 100,000 in all income groups except for high-income countries (1.19 per 100,000).

PRINCIPLES FOR MENTAL HEALTH PROGRAM DEVELOPMENT WORLDWIDE

According to the WHO, the development of mental health programs worldwide should be guided by the following principles: (1) providing treatment in primary care, (2) making psychotropic medications available, (3) giving care in the community, (4) educating the public, (5) involving communities, families, and consumers, (6) establishing national policies and legislations, (7) developing human resources, (8) linking with other relevant sectors, (9) monitoring community mental health, and (10) supporting more research.

Providing treatment in primary care involves the inclusion of recognition and treatment of common mental disorders in training curricula of all health personnel, the provision of refresher training to primary care physicians, and the improvement in referral patterns in primary health care. Making psychotropic medications available includes ensuring the availability of essential drugs in all health care settings and, in high-income countries, providing easier access to newer psychotropic drugs under public or private treatment plans. Giving care in the community implies moving people with mental disorders out of prisons, downsizing mental hospitals and improving care within them, developing general hospital psychiatric units, and providing community care facilities.

Educating the public includes promoting public campaigns against stigma and discrimination; using the mass media to promote mental health, foster positive attitudes, and help to prevent mental disorders; and, in high-income countries, launching public campaigns for the recognition and treatment of common mental disorders. Involving communities, families, and consumers includes supporting the formation of self-help groups, ensuring the representation of communities, families, and consumers in services and policy making, and fostering advocacy initiatives.

Establishing national policies and legislations includes revising legislations on the basis of current knowledge and human rights considerations and increasing the budget for mental health care. Developing human resources involves training psychiatrists and psychiatric nurses and, in middle- and high-income countries, creating national training centers for psychiatrists, psychiatric nurses, psychologists, and psychiatric social workers. Linking with other relevant sectors involves initiating school and workplace mental health programs, encouraging the activities of nongovernmental organizations in those areas, and, in high-income countries, initiating evidence-based mental health promotion programs in collaboration with other appropriate sectors.

Monitoring community mental health involves including mental disorders in basic health information systems, surveying high-risk population groups, instituting surveillance for specific disorders in the community, and, in high-income countries, monitoring the effectiveness of preventive programs. Supporting more research includes conducting studies in primary health care settings on the prevalence, course, outcome, and effect of mental disorders in the community; instituting effectiveness and cost-effectiveness studies for management of common mental disorders in primary health care; and, in high-income countries, carrying out research on the risk factors for mental disorders and on service delivery and investigating evidence on the prevention of mental disorders.

The guiding principles proposed for the prevention of suicide worldwide include (1) reducing access to means of suicide (e.g., pesticides and firearms), (2) treating people with mental disorders, (3) improving media portrayal of suicide, (4) training primary health care personnel, (5) implementing school-based programs, and (6) developing hot lines and crisis centers.

BARRIERS TO CHANGE

The most significant barriers to the implementation of the foregoing principles worldwide, according to the WHO, include the following: (1) some stakeholders may be resistant to the changes, (2) health authorities may not believe in the effectiveness of mental health interventions, (3) there may be no consensus among the country's stakeholders about how to formulate or implement the new policy, (4) financial and human resources may be scarce, (5) other basic health priorities may compete with mental health care for funding, (6) primary care teams may feel overburdened by their workload and refuse to accept the introduction of the new policy, and (7) many mental health specialists may not want to work in community facilities or with primary care teams, preferring to remain in hospitals. The suggested solutions include (1) adopting an "all-winners approach" that ensures that the needs of all stakeholders are taken into account, (2) developing pilot projects and evaluating their effect on health and consumer satisfaction, (3) asking for technical reports from international experts, (4) focusing the implementation of the mental health policy on a demonstration area and performing cost-effectiveness studies, (5) linking mental health programs to other health priorities, and (6) showing primary care practitioners that people with mental disorders are already a hidden part of their burden and that the burden will decrease if these disorders are identified and treated.

STIGMATIZING ATTITUDES TOWARD PEOPLE WITH MENTAL DISORDERS

Stigmatizing attitudes toward people with mental disorders are widespread in the general public and even among mental health professionals. Although it has been suggested that stigma may be less severe in Asian and African countries, a study carried out in India within the Stigma Programme of the World Psychiatric Association (WPA), in which 463 persons with schizophrenia and 651 family members were interviewed in four cities, reported that two-thirds of the respondents had suffered discrimination. Women and people living in urban areas were more stigmatized. Men experienced greater discrimination in the job area, whereas women experienced more problems in the family and social areas. In the family area, subtle discrimination in the form of decreased love, avoidance, rejection, distance, and excessive caution was frequently reported. In Ethiopia, among relatives of people with a diagnosis of schizophrenia or mood disorders, 75% reported that they had experienced stigma due to the presence of mental illness in the family, and 37% wanted to conceal the fact that a relative was ill. In a large survey carried out in China among people with schizophrenia and their family members, one-half of the respondents reported they had felt significantly stigmatized, and levels of stigma were found to be higher in urban areas. Stigmatization of people with mental disorders has been reported to be rare in Islamic countries.

Unlike people with physical disabilities, those with mental disorders are often perceived by the public to be in control of their disabilities and responsible for causing them. The view that “weakness,” “laziness,” or “lack of willpower” contribute to the development of mental disorders has been reported in several countries, including Turkey, Mongolia, and South Africa. The stigmatization of people with mental disorders may result in public avoidance, systematic discrimination, and reduced help-seeking behavior. In a survey carried out in 1996, in a probability sample of 1,444 adults in the United States, more than one-half of the respondents reported being unwilling to spend an evening socializing with, work next to, or have a family member marry a person with mental illness. Although most countries have some provision for disability benefits, people with mental illness are often specifically excluded from such entitlements.

Moreover, mental disorders are frequently not considered in social and private insurance schemes for health care. Shame is reported to be one of the main barriers to seeking help for mental disorders in both developed and developing countries.

A review by Bhugra and colleagues of mental health policies from Commonwealth countries found that less than half of the countries had mental health policies. They also found that there was no equity between funding for mental and physical health disorders. In further analysis global analysis, the research group found that only 11% of countries surveyed had no restriction on voting for persons with mental disorders, with 36% barring voting altogether. Related to the right to marry, 30% of countries surveyed had no restriction, and 37% barred those with mental disorders from getting married. Further, in 12% of countries, mental disorders were grounds for divorce.

Strategies for addressing the stigmatization of people with mental disorders have been subdivided into three groups: protest, education, and contact. There is some evidence that protest campaigns may be effective in reducing stigmatizing behaviors against people with mental disorders. This activist approach may be more workable in some countries rather than in others. Education may promote a better understanding of mental illness, and educated people may be less likely to endorse stigma and discrimination. Even in rural settings in low- and middle-income countries, strategies can be put into place successfully. There is no doubt that certain environments produce higher levels of stigma. These authors reported that internalized stigma and social relationships provide a risk factor for social isolation, especially among patients with schizophrenia. Ungar and colleagues observed that various strategies are needed to deliver antistigma programs, and health care systems themselves need to be included in such efforts. There is no doubt that stigma, whether it is internal or external, will influence help-seeking. Corrigan and colleagues provide a reminder that **s**tigma remains a complex construct. The people who are affected by it and also demonstrate stigma include public, self, and structural components as mentioned above in health care structures. There is no doubt that it directly affects people with mental illness, as well as their support system, provider network, and community resources. These authors also remind readers that cultures influence stigma too. It is likely that cultures see illnesses and idioms of distress in different ways, and stigma may be generated and seen in different ways. Internalized stigma, too, may be affected by cultures, although Pérez-Garín and colleagues point out that well-being can play a major role in mediating stigma. The definitions and understanding of well-being itself can be influenced by cultures. Stigma by professionals themselves deserves further exploration. Poreddi and colleagues report that stigma in medical students can be reduced after they have been exposed to psychiatric teaching and training. It has been suggested that public policy needs to change in order to reduce stigma.

An inverse relationship between having contact with a person with mental illness and endorsing stigmatizing behaviors has been documented. Several recent programs, such as Time to Change in the United Kingdom, have demonstrated that talking with patients with psychiatric illness does lead to a positive change in people's attitudes and changes attitudes in a more positive direction.

RELATIONSHIPS BETWEEN MENTAL AND PHYSICAL DISEASES

Mortality due to physical illness is significantly increased in people with severe mental disorders compared with the general population. In a follow-up study carried out in the United Kingdom, the standardized mortality ratio (SMR) for natural causes in people with schizophrenia was 2.32 (i.e., mortality was more than twice higher than in the general population). The SMR for causes "avoidable by appropriate treatment" was 4.68. The highest SMRs were those for endocrine, nervous, respiratory, circulatory, and gastrointestinal diseases. Increased nonsuicide all-cause mortality has also been reported for bipolar disorder (SMR 1.9 for males and 2.1 for females) and dementia (relative risk [RR] 2.63; 95% confidence interval [CI] 2.17 to 3.21). A meta-analysis of 15 population-based studies of the effect of a diagnosis of depression on subsequent all-cause mortality yielded a pooled odds ratio of 1.7 (CI 1.5 to 2.0). Evidence from low-income countries is limited, but a large population study conducted in Ethiopia found high mortality rates for major depression (SMR 3.55, 95% CI 1.97 to 6.39) and schizophrenia (almost 5% per year).

People with mental illness seem not to have benefited from the recent favorable trends concerning mortality due to some physical diseases. In a longitudinal study conducted in Australia, a steady decline in the mortality rate due to ischemic heart disease was observed in the general population during the period from 1980 to 1998, dropping from 209 to 143 per 100,000 person-years in men and from 139 to 117 per 100,000 person-years in women. In contrast, the mortality rate remained approximately constant in male psychiatric patients (on average 280 per 100,000 person-years) and increased from 153 to 234 per 100,000 person-years in female psychiatric patients.

The prevalence of several physical diseases is increased in people with mental disorders compared with the general population. In a study carried out in the United States, people with psychotic disorders were found to be more likely than other people to develop diabetes, hypertension, heart disease, asthma, gastrointestinal disorders, skin infections, malignant neoplasms, and acute respiratory disorders. The rate was increased even when only patients without a concomitant substance use disorder were considered. In a study conducted in Nigeria, 55.2% of persons with schizophrenia-spectrum disorders referred for the first time to a psychiatric clinic had at least one physical disease, whereas, in persons with neurotic disorders, the rate was 11.8%. A strong prospective association has been documented between depression and coronary heart disease outcomes, including fatal myocardial infarction; on the other hand, the incidence of depression is increased after myocardial infarction, especially in the first month after the event. Depression also increases the risk of type II diabetes. In South Asia, an association between maternal perinatal depression and infant malnutrition and stunting at 6 months has been repeatedly reported.

People with severe mental disorders are at increased risk of contracting HIV infection, although prevalence rates vary substantially worldwide. Conversely, a large multicenter study conducted in sub-

Saharan Africa, Asia, Latin America, Europe, and the United States reported a higher prevalence of depressive disorders among symptomatic HIV-seropositive people than in asymptomatic HIV-seropositive cases and seronegative controls. Evidence from both developed and developing countries shows that adherence to highly active antiretroviral therapy (HAART) is negatively affected by depression, cognitive impairment, and substance abuse.

The increased morbidity and mortality due to physical illness in people with severe mental disorders are first of all related to the increased prevalence in these people of several risk factors for cardiovascular, metabolic, and respiratory diseases, the most important of which are obesity, smoking, and alcohol and drug abuse.

In a study carried out in the United Kingdom, people with severe mental illness were significantly more likely to be obese (body mass index higher than 30) and morbidly obese (body mass index higher than 40) than the general population: The respective figures were 35.0 versus 19.4% and 3.7 versus 1.3%. When these figures were broken down by age and sex, 28.7% of men with severe mental illness aged between 18 and 44 years were obese, compared with 13.6% in the general population, and 3.7% versus 0.4% were morbidly obese. Even more striking were the figures concerning women of the same age: 50.6% versus 16.6% and 7.4% versus 2.0%, respectively.

In a meta-analysis of worldwide studies, a highly significant association between schizophrenia and current smoking was confirmed: The weighted average odds ratio was 5.9; it was 7.2 in males and 3.3 in females. The association remained significant when controls with severe mental illness were used (odds ratio 1.9). Heavy smoking and high nicotine dependence were also more frequent in people with schizophrenia than in the general population.

Patients with severe mental illness have also been reported to make poorer dietary choices and to be less physically active than the general population, but the relevant research evidence is not strong.

The increased risk of HIV infection in people with severe mental disorders may be explained by the high rates of sexual contact with multiple partners, the low levels of condom use, and the high prevalence of injected drug use and sexual contact with partners using injected drugs.

The access of people with mental illness to physical health care is reduced with respect to the general population. In the aforementioned study conducted in Australia, the SMR for ischemic heart disease was found to be 1.78 in men with schizophrenia. However, hospital admission for that disease was remarkably less common in both men and women with schizophrenia compared with the general population. Moreover, both men and women with schizophrenia were more than threefold less likely to receive revascularization procedures than the general population.

The quality of physical health care received by patients with severe mental illness is often worse than the general population. A study conducted in the United States found that adverse events during medical and surgical hospitalizations were significantly more frequent in patients with schizophrenia than in the other people, including infections due to medical care, postoperative respiratory failure, postoperative deep venous thrombosis or pulmonary embolism, and postoperative sepsis. All of these adverse events were associated with a significantly increased odds of admission to an intensive care unit and of death.

The decreased access of people with mental disorders to medical services has been related to several factors concerning the health care system. The effect of lack of insurance and the cost of care is well documented. In a study carried out in the United States, people with mental disorders were twice as likely as those without mental disorders to have been denied insurance because of a pre-existing condition (odds ratio 2.18). Having a mental disorder conferred a greater risk of having delayed seeking care because of cost (odds ratio 1.76) and of having been unable to obtain needed medical care (odds ratio 2.30).

Even when people with mental illness are seen by a doctor, their physical diseases often remain undiagnosed. Primary care providers may misperceive the medical complaints of people with mental disorders as “psychosomatic” or be unskilled or feel uncomfortable in dealing with this population. Underlying stigmatization may be involved. Moreover, during hospitalizations in medical and surgical wards, health care professionals may not be experienced in dealing with the special needs of patients with schizophrenia, may minimize or misinterpret their somatic symptoms, and may make inappropriate use of restraints or sedative drugs or fail to consider possible interactions of psychotropic drugs with other medications. On the other hand, many psychiatrists are unable or unwilling to perform physical and even neurologic examinations or are not up to date on the management of even common physical diseases.

To address this situation, the first step is raising awareness of the problem among mental health care professionals, primary care providers, and patients with schizophrenia and their families. The research information about the increased morbidity and mortality due to physical illness in people with schizophrenia should be appropriately disseminated.

Education and training of mental health professionals and primary care providers is a further essential step. Mental health professionals should be trained to perform at least basic medical tasks. They should be educated about the importance of recognizing physical illness in people with severe mental disorders and encouraged to become familiar with the most common reasons for underdiagnosis or misdiagnosis of physical illness in these patients. On the other hand, primary care providers should overcome their reluctance to treat people with severe mental illness and learn effective ways to interact and communicate with them; it is not only an issue of knowledge and skills but, most of all, one of attitudes.

Another essential step is the development of an appropriate integration between mental health and physical health care. A well-identified professional should be responsible for physical health care for each person with a severe mental disorder. Mental health services should be able to provide at least a standard routine assessment of their patients to identify or at least suspect the presence of physical health problems. Guidelines about the management of patients receiving antipsychotic drugs should be known and applied by all mental health services. Patients should be involved as much as possible; for instance, mental health professionals should encourage patients to monitor and chart their weight. Dietary and exercise programs should be routinely provided by mental health services. Flexible smoking cessation programs, which have shown some degree of success, could be considered in some settings.

ETHICAL ISSUES IN MENTAL HEALTH CARE

The protection and promotion of the human rights of people with mental disorders are emerging as a priority worldwide. In 1991, the United Nations issued Resolution 46/119 for the Protection of Persons with Mental Illness and the Improvement of Mental Health Care. In that resolution, the human rights of people with mental disorders and their right to treatment were codified for the first time in a UN document. The 25 principles covered the following areas: Definition of mental illness; protection of confidentiality; standards of care and treatment, including involuntary admission and consent to treatment; rights of persons with mental disorders in mental health facilities; protection of minors; provision of resources for mental health facilities; the role of community and culture; review mechanisms providing for the protection of the rights of offenders with mental disorders; and procedural safeguards protecting rights of persons with mental disorders. National governments were invited to promote the principles of the resolution by appropriate legislative, juridical, administrative, educational, and other provisions. However, violations of the human rights of people with mental disorders are still reported in many countries, and in a substantial number of low- and middle-income countries, patients in mental hospitals are physically restrained or secluded for long periods.

In Latin America, an influential document has been the Declaration of Caracas, adopted in 1990 by the Regional Conference on Restructuring Psychiatric Care in Latin America, which states that resources, care, and treatment for people with mental disorders should safeguard their dignity and human and civil rights and strive to maintain them people in their communities. The Declaration also states that mental health legislation should safeguard the human rights of people with mental disorders and that services should be organized so that these rights can be enforced.

In Africa, the Banjul Charter on Human and People's Rights, a legally binding document supervised by the African Commission on Human and People's Rights, in Article 5, addresses the right to respect for the dignity inherent in human beings and the prohibition of all forms of degradation, including cruel, inhuman, or degrading treatment.

According to the WHO, mental health legislation should cover the following issues: access to basic mental health care, least restrictive care, informed consent to treatment, voluntary and involuntary admission to treatment, competence issues, periodical review mechanism, confidentiality, rehabilitation, accreditation of professionals and facilities, and rights of families and caregivers.

In 1996, the WPA released the Madrid Declaration, which contains the ethical principles by which all national psychiatric societies are expected to abide. The Declaration includes seven general guidelines focusing on the aims of psychiatry: (1) psychiatrists must serve patients by providing the best therapy available consistent with accepted scientific knowledge and ethical principles and should devise therapeutic interventions that are the least restrictive to the freedom of the patient; (2) it is the duty of psychiatrists to keep abreast of scientific developments of their specialty and to convey updated knowledge to others; (3) the patient should be accepted as a partner by right in the therapeutic process, and the therapist–patient relationship must be based on mutual trust and respect, to allow the patient to make free and informed decisions; (4) treatment must always be in the best interest of the patient, and no treatment should be provided against the patient's will, unless withholding treatment would endanger life of the patient and/or those who surround them; (5) when psychiatrists are requested to assess a person, it is their duty to inform the person being assessed about the purpose of the intervention; (6) information contained in the therapeutic relationship should be kept in confidence and used exclusively for the purpose of improving the mental health of the patient; and (7) because psychiatric patients are particularly vulnerable research subjects, extra caution should be taken to safeguard their autonomy, as well as their mental and physical integrity.

INTERNATIONAL ORGANIZATIONS ACTIVE IN THE MENTAL HEALTH FIELD

There are many international organizations active in the mental health field. They include the WHO, which is the world's leading public health agency; some professional associations, among which the largest is the WPA, representing the psychiatric profession worldwide; and several organizations with a membership of users/families (e.g., the World Fellowship for Schizophrenia and the Global Alliance of Mental Illness Advocacy Networks [GAMIAN]) or of both mental health professionals and users/families (e.g., the World Federation for Mental Health [WFMH]).

The WHO is a UN agency with 193 member states, grouped into six regions (Africa, the Americas, European Mediterranean, Europe, Southeast Asia, and Western Pacific). It has a Department of Mental Health and Substance Abuse at its headquarters in Geneva and advisors for mental health in each of its regional offices. Its main functions are direction and coordination of international health work and technical cooperation with countries. Among the numerous recent WHO activities in the mental health field of special interest are the release of the *mhGAP Intervention Guide (mhGAP-IG)* for use in non-specialist health settings and the development of the report *Mental Health: New Understanding, New Hope*, which was completely devoted to mental health. It provided a summary of the current and projected impact of mental disorders and of the principles of mental health policy and service provision, as well as a set of recommendations for future action that can be adapted to the needs and resources of the various countries. Project Atlas aims to collect information on mental health resources across the world.

The WPA is an association of national psychiatric societies aimed at increasing the knowledge and skills necessary for work in the field of mental health and the care for the mentally ill. Its member societies number 145, spanning 121 countries and representing more than

250,000 psychiatrists. The WPA organizes the World Congress of Psychiatry every 3 years. It also organizes international and regional congresses and meetings, and thematic conferences. It has over 70 scientific sections, which are aimed at disseminating information and promoting collaborative work in specific domains of psychiatry. It has produced several educational programs and a series of books and consensus statements (including the Declaration of Madrid on ethical principles for psychiatric practice). It has an official journal, *World Psychiatry*, which is produced in English, Spanish, and Chinese and is indexed in PubMed and ranked number 1 in Social Science Citation index. Subsequently, several books and information sheets have been published (a full list is available on the WPA website).

The WFMH is a multidisciplinary advocacy and education organization aimed at promoting the advancement of mental health awareness, prevention, advocacy, and best-practice recovery-focused interventions worldwide. Among its activities is the organization of the World Mental Health Day, observed every year on October 10, each time with a different theme.

FUTURE PERSPECTIVES

Several statements have been made by various groups and organizations about priorities for future action in the mental health field at the international level. Of special interest is the aforementioned 2018 Lancet Commission on Global Mental Health and Sustainable Development. In this document, four main foundational pillars are identified: (1) Mental Health is a global public good. In this statement, there is recognition that “all countries can be thought of as developing countries in the context of mental health”, (2) Health problems exist on a continuum, (3) Health is an individual and unique product of social and environmental influences, and (4) Mental health is a fundamental human right that requires a rights-based approach. It is a good step given the focus on wider systems and sustainable development. Indeed, it is explicit in stating that “Although ‘no health without mental health’ is an important aspiration, the era of ‘no sustainable development without mental health’ has begun.”

There are key recommendations made. These include:

1. Reframe mental health within the Sustainable Development Goal Framework
2. Establish mental health care as a pillar of Universal Health Coverage
3. Use public policies to protect mental health
4. Listen to and engage people with lived experience
5. Invest more in mental health
6. Use research to guide innovation and implementation
7. Strengthen monitoring and accountability

It is imperative that local explanatory models and idioms of distress are taken into account so that culturally appropriate, culturally sensitive, and culturally accessible models of service care are developed and delivered. In virtually every country around the world, there are insufficient human and material resources dedicated to the mentally ill and mental illness. In many countries, useful models of engaging the local community exist, and it will be helpful to learn how these work. Furthermore, models using e-mental health and telemental health should be employed, particularly in countries with large geographical areas.

Among the strategies proposed to place mental health on the public health priority agenda are the development and use of uniform and clearly understandable messages for mental health advocacy and the education of decision-makers within governments and donor agencies on the evidence concerning the public health significance of mental disorders and the cost-effectiveness of mental health care. Strategies suggested to improve the organization of mental health services include, among others, the provision of incentive arrangements to overcome vested interests blocking change and the organization of international technical support to learn from countries that have experienced successful mental health reform.

To integrate the availability of mental health in general health care, it is proposed that mental health professionals be appointed and trained specifically for supporting and supervising primary health care staff. To promote the development of human resources for mental health, it is suggested that the professional and specialist workforce be increased and diversified and that the quality of mental health training be improved to ensure that it is practical and also occurs in community or primary care settings. Governments are asked to identify and scale up a priority package of service interventions and to increase mental health budget allocations, with the aim of attaining a minimum level of investment within 10 years of US$ 2 per capita in low-income countries and US$ 3 to 4 per capita in lower-middle–income countries.

International donors and governments of high-income countries, in particular those that are beneficiaries of the brain drain, are asked to place mental health on their priority agenda for health assistance to low- and middle-income countries. Finally, several indicators are proposed to monitor progress worldwide. From 2014 to 2017, WPA has launched an ambitious plan for the social justice for the mentally ill, focusing on domestic gender-based interpersonal violence; child physical and emotional abuse; prisoner mental health care; underserved populations such as asylum seekers, migrants, and refugees; those with intellectual disabilities, lesbian, gay, bisexual, and transgender individuals and older adult individuals and finally developing mental health promotion. Interestingly, World Medical Association is also focusing on child abuse and gender-based violence, and the two organizations are planning to work closely together. WPA is also working with other organizations to develop materials on peri-mental health as well as setting up the WPA-Lancet commission on psychiatry to explore the roles and responsibilities of psychiatrists in the first quarter of the 21st century.

FUTURE DIRECTIONS

This chapter has provided an overview of the burden of mental disorders worldwide, the treatment gap and the scarcity of resources for mental health care, especially in low- and middle-income countries, the WHO guidelines for the development of mental health programs, and the obstacles to their implementation, and several other issues of interest for world psychiatry. The discussion has been based as much as possible on data, although part of the data on world mental health is projections that may under- or overestimate the magnitude of the problems. Moreover, the threshold for the diagnosis of common mental disorders (e.g., depression and anxiety disorders) remains controversial, and although it can be argued that "subthreshold" conditions (not fulfilling current diagnostic criteria) might be a further neglected source of burden and disability, it can also be pointed out that some conditions fulfilling current diagnostic criteria might represent homeostatic reactions to adverse life events that are transient and do not require treatment. The threshold for the diagnosis of common mental disorders may be different in the various geographic and cultural contexts, making projections and international comparisons even more problematic. On the other hand, although several pharmacologic and psychotherapeutic interventions have been proved to be efficacious in various regions of the world, their feasibility and acceptability may not be the same worldwide, and current treatment guidelines may not be relevant to people living in several low- and middle-income countries. The same may apply to rehabilitation programs and models of community mental health care. The fact is that, although around 85% of the world's population lives in low- and middle-income countries, only a negligible proportion of research in the mental health field is conducted in those countries. Research-generated information is crucial to evaluate local needs, develop cost-effectiveness interventions, and monitor their implementation. Several initiatives are now addressing this research gap, and it can be hoped that a substantial revision of this chapter will be needed in the near future.

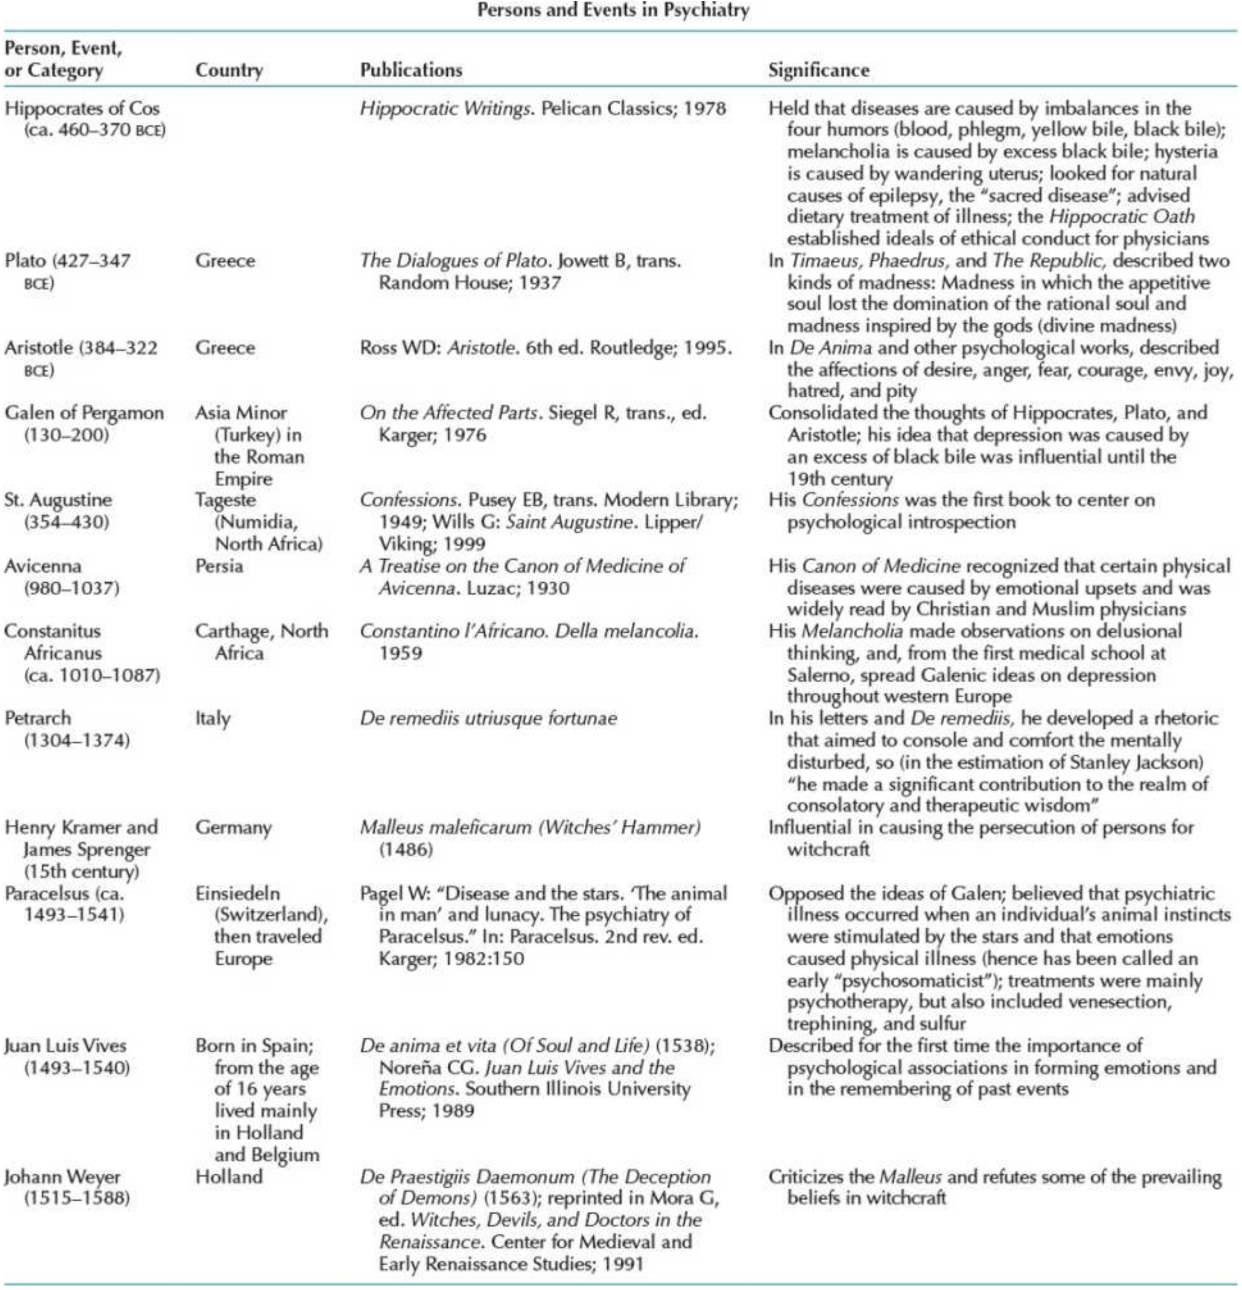
Appendix A

History of Psychiatry Table

Persons and Events in Psychiatry



Persons and Events in Psychiatry

Person, Event, or Category	Country	Publications	Significance
Hippocrates of Cos (ca. 460–370 BCE)		*Hippocratic Writings*. Pelican Classics; 1978	Held that diseases are caused by imbalances in the four humors (blood, phlegm, yellow bile, black bile); melancholia is caused by excess black bile; hysteria is caused by wandering uterus; looked for natural causes of epilepsy, the "sacred disease"; advised dietary treatment of illness; the *Hippocratic Oath* established ideals of ethical conduct for physicians
Plato (427–347 BCE)	Greece	*The Dialogues of Plato*. Jowett B, trans. Random House; 1937	In *Timaeus, Phaedrus,* and *The Republic,* described two kinds of madness: Madness in which the appetitive soul lost the domination of the rational soul and madness inspired by the gods (divine madness)
Aristotle (384–322 BCE)	Greece	Ross WD: *Aristotle*. 6th ed. Routledge; 1995.	In *De Anima* and other psychological works, described the affections of desire, anger, fear, courage, envy, joy, hatred, and pity
Galen of Pergamon (130–200)	Asia Minor (Turkey) in the Roman Empire	*On the Affected Parts*. Siegel R, trans., ed. Karger; 1976	Consolidated the thoughts of Hippocrates, Plato, and Aristotle; his idea that depression was caused by an excess of black bile was influential until the 19th century
St. Augustine (354–430)	Tageste (Numidia, North Africa)	*Confessions*. Pusey EB, trans. Modern Library; 1949; Wills G: *Saint Augustine*. Lipper/ Viking; 1999	His *Confessions* was the first book to center on psychological introspection
Avicenna (980–1037)	Persia	*A Treatise on the Canon of Medicine of Avicenna*. Luzac; 1930	His *Canon of Medicine* recognized that certain physical diseases were caused by emotional upsets and was widely read by Christian and Muslim physicians
Constanitus Africanus (ca. 1010–1087)	Carthage, North Africa	*Constantino l'Africano. Della melancolia.* 1959	His *Melancholia* made observations on delusional thinking, and, from the first medical school at Salerno, spread Galenic ideas on depression throughout western Europe
Petrarch (1304–1374)	Italy	*De remediis utriusque fortunae*	In his letters and *De remediis,* he developed a rhetoric that aimed to console and comfort the mentally disturbed, so (in the estimation of Stanley Jackson) "he made a significant contribution to the realm of consolatory and therapeutic wisdom"
Henry Kramer and James Sprenger (15th century)	Germany	*Malleus maleficarum (Witches' Hammer)* (1486)	Influential in causing the persecution of persons for witchcraft
Paracelsus (ca. 1493–1541)	Einsiedeln (Switzerland), then traveled Europe	Pagel W: "Disease and the stars. 'The animal in man' and lunacy. The psychiatry of Paracelsus." In: Paracelsus. 2nd rev. ed. Karger; 1982:150	Opposed the ideas of Galen; believed that psychiatric illness occurred when an individual's animal instincts were stimulated by the stars and that emotions caused physical illness (hence has been called an early "psychosomaticist"); treatments were mainly psychotherapy, but also included venesection, trephining, and sulfur
Juan Luis Vives (1493–1540)	Born in Spain; from the age of 16 years lived mainly in Holland and Belgium	*De anima et vita (Of Soul and Life)* (1538); Noreña CG. *Juan Luis Vives and the Emotions*. Southern Illinois University Press; 1989	Described for the first time the importance of psychological associations in forming emotions and in the remembering of past events
Johann Weyer (1515–1588)	Holland	*De Praestigiis Daemonum (The Deception of Demons)* (1563); reprinted in Mora G, ed. *Witches, Devils, and Doctors in the Renaissance*. Center for Medieval and Early Renaissance Studies; 1991	Criticizes the *Malleus* and refutes some of the prevailing beliefs in witchcraft

Juan Huarte de San Juan (ca. 1530–1592)	Spain	*The Examination of Men's Wits* (1575)	An early account of differences in temperaments and dispositions
Giambattista Porta (1535–1615)	Italy	*De humana physiognomia* (1586)	Gave to physiognomy the air of at least a pseudoscience
Felix Plater (1536–1614)	Switzerland	*Practice of Medicine* (1602); *Observations of Diseases Injurious to Body and Mind* (1614)	New classification of diseases based on symptoms, causes, and treatments; careful description of all known psychiatric and organic diseases; the first physician to separate medicine from philosophy and make it a branch of natural science; a pioneer in studying the behavior and neuropathology of the persons with mental handicaps
Robert Burton (1577–1640)	England	*The Anatomy of Melancholy* (1621)	The most famous book on psychiatry in the 17th century; a comprehensive presentation of all previous medical-psychological thought on melancholy, also drawing on the nonmedical literature of Western civilization
Paolo Zacchia (1584–1659)	Italy	*Questiones medico-legales* (1621–1635)	Held that a physician, rather than a priest or lawyer, should evaluate a patient's responsibility for disturbed behavior; the beginning of forensic psychiatry
Thomas Sydenham (1624–1689)	England	Dissertatio epistolaris … [1682]. In: The Entire Works of Dr. Thomas Sydenham Newly Made English (1742)	Gave a comprehensive picture of the many symptoms of hysteria, believing that in the form of hypochondriacal complaints, it could exist in men and that it was caused by disturbed animal spirits; his approach to classifying the causes of symptoms resembled the modern psychiatric endeavor of constructing atheoretical classifications of psychiatric illnesses
Thomas Willis (1621–1675)	England	*Two Discourses Concerning the Soul of Brutes* (1683)	Summarized what was known about major psychiatric illnesses; recognized differences in illnesses when there was gross brain disease and when the brain seemed normal, attributing the latter to disturbed animal spirits; attributed hysteria to disturbed animal spirits acting on the brain, not to a wandering uterus
Georg Ernst Stahl (1660–1734)	Germany	*Theoria medica vera* (1707), *De animi morbis* (1708)	Theory of animism; the soul, *anima,* maintains functions of body in health and disease; psychiatric illness is caused either by inhibitions of anima or diseases of the body
William Battie (1703–1776)	England	*A Treatise of Madness* (1758)	First physician who made insanity his full work, raised "the mad business" to a respected specialty, and first used "madness" in the title of his book
Boissier de Sauvages (1706–1767)	France	*Nosologia methodica* (1765)	Nosology divided diseases into classes based on symptoms; although speculative and artificial, it stimulated a rethinking of concepts of disease
John Aiken (1747–1822)	England	*Thoughts on Hospitals* (1771)	First book on hospitals in which "lunatic hospitals" were discussed
Franz Anton Mesmer (1734–1815)	Austria, France	*Memoire sur la découverte du magnetism animal* (1779)	Showed that when a mental therapist used the so-called animal magnetism, it could cure cases of psychiatric illness; led to the discovery of hypnosis
Vincenzo Chiarugi (1759–1820)	Italy	*Regulations of the Hospitals of Santa Maria Nuova and of Bonifazio* (1789)	One of the first attempts to treat the insane inmates of asylums humanely and without restraints
William Cullen (1710–1790)	Scotland	*Nosology, or a Systematic Arrangement of Diseases* (1800)	A great 18th century nosologist who first used the terms *neurosis* and *neurotic* to describe mental diseases
Philippe Pinel (1745–1826)	France	*A Treatise on Insanity in Which Are Contained the Principles of a New and More Practical Nosology of Mental Disorders* (1801)	Classified mental illness into four main forms and established a new, humane treatment for inmates of insane asylums, which he called "the moral treatment of insanity"
Johann Reil (1759–1813)	Germany	*Rhapsodies about the Application of Psychotherapy to Mental Disturbances* (1803)	The founder of rational psychotherapy, recognizing the therapeutic value of institutional surroundings, music, psychodrama, and occupational therapy; first used the word *psychiatry,* and founded the first psychiatric journal
Benjamin Rush (1745–1813)	United States	*Medical Inquiries and Observations upon the Diseases of the Mind* (1812); Farr C. Benjamin Rush and American psychiatry. *Am J Psychiatry*. 1994;151(Suppl):65	The most famous American physician of his time and the only physician to sign the Declaration of Independence; the first American author of a book on general psychiatry; and the father of American psychiatry. A vocal abolitionist, his legacy is complicated by the fact he owned a slave, William Grubber. Similarly, although he argued for the equality of African Americans, he also wrote that Black people's skin was a type of leprosy.
Thomas Sutton (1767–1835)	England	*Tracts on Delirium Tremens* (1813)	First description of alcoholic delirium tremens

William Tuke (1732–1822); Samuel Tuke (1784–1857), grandson of William Tuke; Daniel Hack Tuke (1827–1895), youngest son of Samuel Tuke; John Charles Bucknill (1817–1895)	England	Tuke S. Description of the Retreat, an Institution near York, for Insane Persons of the Society of Friends. York; 1813; Tuke DH, Bucknill JC. *A Manual of Psychological Medicine Containing the History, Nosology, Description, Statistics, Diagnosis, Pathology, and Treatment of Insanity*. 1858	W. Tuke founded the York Retreat for the moral treatment of mentally ill Quakers in 1796; S. Tuke's *Description of the Retreat* influenced asylum treatment in England, Europe, and the United States; the *Manual* of D. Tuke and Bucknill was the first comprehensive textbook of psychiatry
Joseph Adams (1756–1818)	England	*A Treatise on the Supposed Hereditary Properties of Diseases … Particularly in Madness and Scrofula* (1814)	First book on the hereditary properties of diseases; argued that it was not a disease that was inherited but a susceptibility to diseases; therefore, prevention and cure were possible
Franz Joseph Gall (1758–1828), Johann Gaspar Spurzheim (1776–1832)	Austria, Germany	*The Physiognomical System of Drs. Gall and Spurzheim; founded on an anatomical and physiological examination of the nervous system in general and of the brain in particular* (1815)	The beginning of phrenology: Mapping parts of the brain, defining their psychological functions, and making psychological and psychotherapeutic predictions
Johann Christian Heinroth (1773–1843)	Germany	*Disturbances of the Mind* (1818); Hansen LA. Metaphors of mind and society: The origins of German psychiatry in the revolutionary era. *Isis*. 1998;89:387; Cauwenbergh LS. *J Chr A Heinroth* (1773–1843) a psychiatrist of the German Romantic era. *Hist Psychiatry*. 1991;2:365	First systematic textbook of psychiatry that attempted to formulate an actual clinical system of psychotherapy; the first to use the word *psychosomatic* and the first to hold a chair in psychological medicine at the University of Leipzig
Robert Gooch (1784–1830)	England	*An Account of … Diseases Peculiar to Women* (1829)	First account of postpartum psychosis
James Cowles Pritchard (1786–1848)	England	*A Treatise on Insanity and Other Disorders Affecting the Mind* (1835)	Standard textbook of psychiatry covering all of the literature on all known diseases; described moral insanity, later called *psychopathic personality*
Jean Etienne Dominique Esquirol (1782–1840)	France	*Mental Maladies: A Treatise on Insanity* (1838)	Coined the term *hallucination,* described "idiocy," classified insanities into monomania (partial insanity) and general delirium, and recognized both emotional and organic causes of illness; one of the authors of a comprehensive law providing an asylum for every department of France
Isaac Ray (1807–1881)	United States	*Treatise on Medical Jurisprudence of Insanity* (1838)	Founded American forensic psychiatry
James Braid (1795–1860)	England	*Neurypnology; or, the Rationale of Nervous Sleep* (1843)	Entirely separated hypnotism from animal magnetism and began the study of hypnotic phenomena
Daniel M'Naghton (1813–1865)	England	West DJ, Walk A, eds. *Daniel M'Naghton: His Trial and the Aftermath*. London Gaskell Books; 1977	Suffering from persecutory delusions, M'Naghton murdered the secretary of a government official in 1843; at his murder trial, he was ruled not guilty by reason of insanity and was committed to an insane asylum for the rest of his life; the "M'Naghton rule" has influenced English and American legal criteria for acquittal on the basis of insanity
Wilhelm Griesinger (1817–1868)	Germany	*Mental Pathology and Therapeutics* (1845)	Proclaimed that psychiatric diseases are brain diseases and that psychiatry had become a medical specialty
Jacques-Joseph Moreau de Tours (1804–1884)	France	*Du haschich et de l'aliénation mentale* (1845)	Described the effects of his taking hashish, and became the first psychiatrist to experience a drug-induced psychosis
Diversity, Equity, Inclusion, and Justice	United States	Samuel Cartwright presents a report to the Medical Association of Louisiana in 1851	Dr. Cartwright proposed the mental illness of "drapetomania," or the dissatisfaction of slaves with their condition and their resulting tendency to run away. He also coined the term dysaesthesia aethiopica, a supposed disorder that explains the lack of work ethic among slaves.
Walter Cooper Dendy (1794–1871)	England	Psychotherapeia, or the remedial influence of mind. *J Psychol Med Ment Pathol*. 1853;6:268	First introduced the term *psychotherapeia* (psychotherapy), which he defined as prevention and remedy of disease by psychical influence and which he predicted would become valuable in psychiatry

Jean-Pierre Falret (1794–1870), Jules Baillarger (1809–1890)	France	Baillarger J. La folie à double forme. *Bull Acad Imp Med.* 1853–1854;19:340; Falret JP. La folie circulaire. *Bull Acad Imp Med.* 1853–1854;19:382; Pichot P. The birth of the bipolar disorder. *Eur Psychiatry*. 1995;10:1	Baillarger and Falret called bipolar disorder "double insanity" and "circular insanity"; in 1899, Kraepelin named this illness *manic-depressive psychosis*
Thomas Kirkbride (1809–1883)	United States	*On the Construction, Organization, and General Arrangements of Hospitals for the Insane* (1854)	Set a standard for mid-19th century care of the chronically insane that commands respect today
John Conolly (1794–1866)	England	*The Treatment of the Insane without Mechanical Restraints* (1856)	Conolly's work for the nonrestraint system marked the success of a movement that began with Pinel and created a new approach to treating insanity throughout the civilized world
George Robinson (1821–1875)	England	*On the Prevention and Treatment of Mental Disorders* (1859)	Introduced the idea of looking beyond the precincts of the asylum to prevent mental illness
Gustav Theodor Fechner (1801–1887)	Germany	*Elements of Psychophysics* (1860)	Established the relationship between the intensity of stimuli and sensory reactions; called the founder of experimental psychology
Benedict-Augustin Morel (1809–1873)	France	*Traité des maladies mentales* (1860)	Presented cases of insanity and other mental illnesses caused by inherited "mental degeneration" that became worse from one generation to the next
Thomas Laycock (1812–1876)	England	*Mind and Brain* (1860)	Mentioned unconscious functional activity of the brain but did not further develop the idea
Forbes B. Winslow (1810–1874)	England	*On Obscure Diseases of the Brain and Disorders of the Mind* (1860)	First to mention psychical diagnostic tests (psychological tests) and the psychiatric interview
Ewald Hecker (1843–1909)	Germany	Die Hebephrenie. *Arch Pathol Anat Physiol.* 1871:52	First description of "hebephrenia" (later a subgroup of dementia praecox)
Karl Kahlbaum (1828–1899)	Germany	*Die Katatonie oder das Spannungsirresein* (Berlin, 1874)	First description of catatonia (later a subgroup of dementia praecox)
George Miller Beard (1840–1883)	United States	*A Practical Treatise on Nervous Exhaustion (Neurasthenia)* (1880)	Neurasthenia—a disease of mental and physical exhaustion—replaced the diagnosis of hypochondriasis; it became prevalent in the American and European upper classes from approximately 1870 to 1920
Richard von Krafft-Ebing (1840–1902)	Germany	*Psychopathia sexualis* (1886); Oosterhuis H. *Stepchildren of Nature: Kraft-Ebing, Psychiatry, and the Making of Sexual Identity*. C University of Chicago Press; 2000	Described cases of homosexuality and sexual perversions, claiming that some were caused by degeneration, and coined the terms *sadism, masochism,* and *sexual bondage; Psychopathia* was respected by lawyers and scientists, and it founded the science of sexology
Pierre Janet (1859–1947)	France	*L'automatisme psychologique: Essai de psychologie experimentale sur les formes inferieures de l'active* (Paris, 1889); van der Kolk BA, van der Hart O. Pierre Janet and the breakdown of adaptation in psychological trauma. *Am J Psychiatry*. 1989;146:1530	Showed that severe traumatic experiences caused two types of dissociative symptoms—*hysteria,* with dissociations of feelings or memories related to the experiences, and *psychasthenia,* with obsessions, phobias, and anxieties; the first systematic attempt to show how the mind can dissociate in the face of severe trauma
Herman Emminghaus (1845–1904)	Germany	*Psychic Disturbances of Childhood* (1887)	First textbook of child psychiatry
Jean-Martin Charcot (1825–1893)	France	Owen ARG. *Hysteria, Hypnosis, and Healing: The Work of JM Charcot.* Garrett Publications; 1971; by Goetz C, Bonduelle M, Gelfand T. *Charcot: Constructing Neurology*. Oxford University Press; 1995	In 1882, became the first professor of diseases of the nervous system at the University of Paris, helping to institutionalize neurology as a medical specialty and making Paris an international center for neurologic studies; although he erroneously believed that only hysterics could be hypnotized, he fully delineated and classified the protean manifestations of hysteria, and he was the first to give a psychological account of hysteria and show that some of its symptoms are the result of ideas that dominated the mind of the hysteric
Georges Gilles de la Tourette (1857–1904)	France	Etude sur une affection nerveuse caractérisée par l'incoordination motrice accompagnée d'echolalie et coprolalie. *Arch Neurol* (Paris). 1885;ix:19, 158; Yorston G, Hindley N, trans. and intro: Study of a nervous disorder characterized by motor incoordination with echolalia and coprolalia. *Hist Psychiatry.* 1998;9:97; Kushner HI. *A Cursing Brain? The Histories of Tourette Syndrome*. Harvard University Press; 1999	Described a syndrome of involuntary movements and echolalia and coprolalia in nine patients, seven of whom were at the Paris Hôpital de la Salpêtrière, where he was a resident neurologist in training; Jean-Martin Charcot, director of the Salpêtrière and France's leading neurologist, then sanctioned the use of de la Tourette's name for the syndrome

Cesare Lombroso (1835–1909)	Italy	*Genius and Insanity* (1864), *The Delinquent Man* (1876), *The Female Offender* (1893)	Emphasized the study of the individual personality, which gave rise to pathographies—psychopathologically oriented biographies; his books on delinquent men and women stimulated a school of criminal anthropology that engendered the science of criminology
Emil Kraepelin (1856–1926)	Germany	Kraepelin E. *Psychiatrie: Ein Lehrbuch für Studerende und Aerzte*. 6th ed. (1899); *Memoirs*. Springer-Verlag; 1987	Divided the major psychoses into two groups: Dementia praecox, which deteriorated to dementia, and manic-depressive psychosis, which did not deteriorate
John Hughlings Jackson (1834–1911)	England	*Selected Writings of John Hughlings Jackson* (London, 1931–1932)	From 1870 to 1900, developed the thesis that psychiatric symptoms are a regression from higher functions that are the products of evolution; the symptoms resulted from activating more primitive functions
Sigmund Freud (1856–1939)	Austria	*The Interpretation of Dreams* (1900), *Three Essays on the Theory of Sexuality* (1905), *Introductory Lectures on Psychoanalysis* (1915–1917)	Discovered the manifestations of the unconscious and how to use them in treating psychiatric patients; described infantile sexuality and how it accounted for adult sexual dysfunctions; founded psychoanalysis
Morton Prince (1854–1929)	United States	*The Dissociation of a Personality* (1905)	Early account of a multiple personality; emphasized techniques of hypnosis and manifestations of the unconscious
Clifford Beers (1876–1943)	United States	*A Mind That Found Itself* (1908)	Account of experiences in psychiatric hospitals that stimulated the mental hygiene movement in the United States
Eugen Bleuler (1857–1939)	Switzerland	*Dementia Praecox or the Group of Schizophrenias* (1911)	Coined the term *schizophrenia* and described its symptoms
Alfred Binet (1857–1911)	France	*A Method of Measuring the Development of the Intelligence of Young Children*, with T. Simon (1911); English translation, 1913	Developed the first practicable intelligence test for children; it has become the prototype for subsequent tests of intellectual ability in children and adults
Hideyo Noguchi (1876–1928)	United States	Noguchi H, Moore JW. A demonstration of the *Treponema pallidum* in the brain in cases of general paralysis. *J Exp Med*. 1913:17	The definitive demonstration, after a century of controversy, that the syphilitic organism causes general paresis; the first time that the cause of a major psychosis became known
Alfred Adler (1870–1937)	Austria	*Study of Organ Inferiority and Its Psychical Compensations* (1917); Stepansky PE. *In Freud's Shadow: Adler in Context*. Analytic Press; 1983	First psychoanalytic defector from Freud; founded the school of individual psychology and coined the terms *life style* and *inferiority complex*
Hermann Rorschach (1884–1922)	Switzerland	*Psychodiagnostik* (1921)	Inkblot test revealed unconscious motivations and ego defenses against them and was used for psychiatric diagnosis; it stimulated the development of other projective diagnostic tests
Julius von Wagner-Jauregg (1857–1940)	Austria	de Rudoli G. *Therapeutic Malaria* (1927); Wagner-Jauregg J. The history of the malaria treatment of general paresis. *Am J Psychiatry*. 1994;151(Suppl):231; Brown EM. Why Wagner-Jauregg won the Nobel Prize for discovering malaria therapy for general paresis of the insane. *Hist Psychiatry*. 2000;11:371	During the decade 1917–1927, showed that general paresis patients underwent remissions when malaria was induced; for the time, it was the most successful organic treatment of a psychosis; for that, he became, in 1927, the first psychiatrist to receive the Nobel Prize; in the 1940s, penicillin became the treatment of choice for paresis
Otto Rank (1884–1939)	Austria, France, United States	*The Myth of the Birth of the Hero* (1909), *The Trauma of Birth* (1924), *Will Therapy* (1936); Lieberman EJ. *Acts of Will: The Life and Work of Otto Rank*. Free Press, Macmillan; 1985	Made important contributions to Freudian psychoanalysis by showing how a person's wishes and fantasies influenced the formation of human myths; breaking with Freud, Rank formed his theory of how the experience of birth influenced a person's mental development and then his technique of will therapy
American Board of Psychiatry and Neurology (ABPN)	United States	Freeman W, Ebaugh F, Boyd D Jr. The founding of the American Board of Psychiatry and Neurology, Inc. *Am J Psychiatry*. 1959;115:769	In 1934, a group of prominent American psychiatrists and neurologists founded the ABPN, comprising equal numbers of psychiatrists and neurologists, with separate qualifications and examinations for psychiatrists and neurologists; the qualifications for psychiatrists included 3 years of study of psychiatry after an internship, and 2 years of hospital practice in psychiatry; the original purpose of the ABPN was, in the words of Walter Freeman, "to create standards of ethical practice and professional competence based on adequate fundamental education in the field"; since its founding, it has maintained these standards while keeping abreast of advances in information and technology

Henry A. Murray (1893–1988)	United States	*Thematic Apperception Test*. Harvard University Press; 1943	The Thematic Apperception Test, originated in 1935, is a method used for uncovering conscious and unconscious dominant themes in a person's mental life
Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United Kingdom	The Indian division of the Royal Medico-Psychological Association is formed in 1935.	
Charles Bradley (1902–1979)	United States	Bradley C. The behavior of children receiving Benzedrine. *Am J Psychiatry*. 1937:577; Gross MD. Origin of stimulant use for treatment of attention deficit disorder. *Am J Psychiatry*. 1995;152:298	The first physician to record the successful treatment of what came to be called attention-deficit disorder in children with stimulant medications
Cure of pellagra	United States	Roe D. *A Plague of Corn: The Social History of Pellagra*. Cornell University Press; 1973	Pellagra is a niacin-deficiency disease manifested by diarrhea, dermatitis, and dementia; in the South, it was caused by removal of niacin in the milling of corn and was a major cause of dementia; in 1912, Joseph Goldberger (1874–1929), of the U.S. Public Health Service, proved that pellagra was caused by absence of a pellagra-preventive factor in the diet; in 1937, that factor was identified as niacin; since then, with niacin-enriched diets, pellagra has largely vanished; pellagra has also occurred in other countries whose staple grain is maize (American corn)
Genetics of schizophrenia	Germany, United States	Rüdin E. *Studien über Verebung und Entstehung geistiger Störungen. I. Zur Vererbung und Neuetstehung der Dementia Praecox. [Studies on the Heredity and Genesis of Mental Diseases. I. On the Heredity and New Formation of Dementia Praecox.]* Berlin: Verlag von Julius Springer; 1916; Kallman FJ. *The Genetics of Schizophrenia*. JJ Augustin; 1938; Rainer JD. The contributions of Franz J. Kallmann to the genetics of schizophrenia. In: Cancro R, Dean SR, eds. *Research in the Schizophrenic Disorders: The Stanley R. Dean Award Lectures*. Vol. 2. Spectrum; 1985	Rüdin (1874–1952) and Kallman (1897–1965) showed that schizophrenia was transmitted by recessive genes (although they differed over how these genes exerted their effects); Kallman first worked under Rüdin in the Max Planck Institute of Psychiatry in Munich, then studied the incidence of schizophrenia among the siblings and descendants of 1,087 hospitalized schizophrenic patients in two Berlin hospitals; when he emigrated to the United States in 1936, he brought the German manuscript of his book on these patients; it was translated into English in 1938 and became a pioneering work; Kallman spent the rest of his life working at the New York Psychiatric Institute, where he established the first full-time medical genetics department in a U.S. psychiatric institution
ECT	Italy	Abrams R. The treatment that will not die. *Psychiatr Clin North Am*. 1994;17:525; Berrios G. The scientific origins of electroconvulsive therapy: A conceptual history. *Hist Psychiatry*. 1997;8:105	Two Italian psychiatrists, Ugo Cerletti (1897–1963) and Lucio Bini (1908–1964), first used ECT in Rome in 1938 to produce convulsions that alleviated symptoms in a schizophrenic patient; it was then found to be more effective in mood disorders than in schizophrenia, and although its use has declined because of psychotropic drugs, modified forms of ECT are used today
Karen Horney (1885–1952)	Germany until 1932, then United States	*The Neurotic Personality of Our Time* (1937), *New Ways in Psychoanalysis* (1939), *Neurosis and Human Growth: The Struggle Toward Self-Realization* (1950); Paris B. Karen Horney: *A Psychoanalyst's Search for Self-Understanding*. Yale University Press; 1994	Opposed Freud's theory of the castration complex in women and his emphasis on the oedipal complex and sexuality as influencing neurosis; argued that neurosis was influenced by the culture of the society in which one lived
Adolf Meyer (1866–1950)	Switzerland until 1893, then United States	Meyer A. A short sketch of the problems of psychiatry. *Am J Insanity*. 1896–1897;53: 538; Lidz T. Adolf Meyer and the development of American psychiatry. *Am J Psychiatry*. 1996;123:320; Adolf Meyer. In: Havens L, ed. *Approaches to the Mind*. Little, Brown.	From 1912 to 1940, the dominant figure in American psychiatry; his concept of psychobiology viewed the patient as a biologic and psychological unity who became ill because of internal pathology and maladaptations to the environment; he treated patients with medical and nonmedical therapies in community clinics; his work has become part of present-day American psychiatry
Constitution, personality, and mental illness	Germany, United States	Kretschmer E. Body Build and Character (1922); Sheldon WH. Varieties of Human Physique (1940)	Kretschmer (1888–1964) and Sheldon (1899–1977) postulated that thin, asthenic individuals were prone to introversion, schizoid tendencies, and schizophrenia, whereas individuals who were short and round were predisposed to be extroverts and had cyclothymic personalities and manic depression; there are many exceptions to these postulates

Führer decree (1939)	Germany	Lifton RJ. The Nazi doctors. In: "Euthanasia": *Direct Medical Killing*. Basic Books; 1986: Chapter 2; Gallagher HG. *By Trust Betrayed: Patients, Physicians, and the License to Kill in the Third Reich*. Henry Holt; 1990; Annas GJ, Grodin MA, eds. *The Nazi Doctors and the Nuremburg Code. Human Rights in Human Experimentation*. Oxford University Press; 1992	In October 1939, soon after the outbreak of World War II, a Führer decree ordered doctors to kill patients who had incurable medical illnesses (this grew out of the Nazi doctrine of preserving racial purity by eliminating those who were "biologically unfit"); during the course of the war, approximately 270,000 mental patients were killed by physicians and medical personnel; Henry Friedlander postulated in *The Origins of Nazi Genocide: From Euthanasia to the Final Solution* (1995) that these medical killings, which began in 1940, served as a stimulus and practical model for the Nazi genocide of Jews and Gypsies that began in 1941
MMPI	United States	Buchanan R. The development of the Minnesota Multiphasic Personality Inventory. *J Hist Behav Sci*. 1994;29:148	The MMPI, developed by S. R. Hathaway (1903–1984) and J. C. McKinley (1891–1950) at the University of Minnesota during the early 1940s, became the most widely used and researched psychological personality measurement device; a revised version of the MMPI, MMPI-2, was published in 1989; in 1999, a third edition of MMPI-2 was published, containing the results of new research studies along with a new chapter on forensic applications of MMPI-2
Leo Kanner (1894–1981)	Austria, United States	Child Psychiatry. Springfield, IL: CC Thomas; 1935; Autistic disturbances of affective contact. *Nerv Child*. 1943;2:217	The first English-language textbook of child psychiatry and a pioneering description of what Kanner later called "early infantile autism"
Melanie Klein (1882–1960), Anna Freud (1895–1982)	Central Europe, then England	Klein M. *The Psychoanalysis of Children* (1932); Kernberg O. Melanie Klein. In: Kaplan HI, Freedman AM, Sadock BJ, eds. *Comprehensive Textbook of Psychiatry*. 3rd ed. Williams & Wilkins; 1980; Grosskurth P. *Melanie Klein: Her World and Her Work*. Knopf; 1986; Freud A. *The Ego and the Mechanisms of Defence* (1936), *The Psychoanalytic Treatment of Children* (1946), A short history of child analysis. *Psychoanal Study Child*. 1966;21:7; Young-Bruehl E. *Anna Freud: A Biography*. Summit Books; 1988	Klein and A. Freud were pioneers in originating different concepts of child psychoanalysis; Klein's concepts of the "paranoid-schizoid and depressive positions" of very young children has influenced child psychiatry and the treatment of adult borderline and psychotic patients; A. Freud formulated a group of basic concepts of child psychoanalysis and extended the ego psychology work of her father, Sigmund Freud, by delineating the ego defenses, including "identification with the aggressor"
Helene Deutsch (1884–1982)	Europe until 1935, then United States	*The Psychology of Women*, 2 vols. (1945); some forms of emotional disturbance and their relationship to schizophrenia ("As If"). In: Deutsch H, ed. *Neuroses and Character Types*. International Universities Press; 1965: Chapter 20; Roazen P. *Helene Deutsch: A Psychoanalyst's Life*. Anchor Press/Doubleday; 1985	For several decades the most comprehensive Freudian view of the life cycle of women; her most famous clinical concept was the "as if" personality: An apparently normal person who gives a good semblance of adaptation to reality, yet is actually devoid of genuine emotion
Ivan Petrovich Pavlov (1849–1936), Andrew Salter (1914–1996)	Russia, United States	Pavlov IP. *Lectures on Conditioned Reflexes*. 2 vols. International Publishers; 1941; Babkin, BP. *Pavlov: A Biography*. University of Chicago Press; 1949; *Salter A. Conditioned Reflex Therapy*. Farrar, Straus; 1949	From 1903 to 1936, Pavlov showed how conditioned reflexes influence normal and pathologic thought; Salter then applied conditioned reflex therapy to psychiatric patients by postulating that neuroses result from an excess of cortical inhibition and by emphasizing assertion training; his therapy became one trend in the development of behavioral therapy
NMHA (1946), NIMH (1949)	United States	Grob GN. *From Asylum to Community: Mental Health Policy in Modern America*. Princeton University Press; 1991: Chapters 2–4. Romano J. Reminiscences: 1938 and since. *Am J Psychiatry*. 1990;147:785	Congressional passage in 1946 of the NMHA provided American psychiatry for the first time with generous funds for psychiatric education and research, and led to the creation of the NIMH in 1949, with goals of research in schizophrenia and training of mental health personnel
Organizational Psychiatry	India	The Indian Psychiatric Society is Established in 1947	
Popular Media	United Statues	The Snake Pit, by Mary Jane Ward is published in 1946. A movie adaptation is released in 1948, sparking a call for reforms to the U.S. state psychiatric hospital system.	

Erik H. Erikson (1902–1994)	Europe; United States since 1930s	*Childhood and Society* (1950), *Identity and the Life Cycle* (1959); Friedman LJ. *Identity's Architect: A Biography of Erik H. Erikson.* Scribner; 1999; Wallerstein R, Goldberger L, eds. *Ideas and Identities: The Life and Work of Erik Erikson.* International Universities Press; 1999	Restated Freud's concepts of infantile sexuality, developed concepts of adult identity and identity crisis, and applied psychoanalytic concepts to U.S. cultural life and political history; his *Young Man Luther: A Study in Psychoanalysis and History* (1958) influenced the writing of psychohistory
Carl Rogers (1902–1987)	United States	*Client-Centered Theory* (1951)	Showed that in many patients there existed constructive mental forces that had been previously unrecognized and unemployed and that a therapist, through the use of insight and catharsis, could aid a patient to use these forces to make beneficial changes in his or her life; the approach marked the beginning of a shift of psychotherapy from physicians and psychoanalysts to clinical psychologists and psychiatric social workers
Donald Winnicott (1896–1971)	England	Winnicott D. Transitional objects and transitional phenomena [1951]. In: *Collected Papers: Through Paediatrics to Psychoanalysis*. Tavistock, 1958; Kohon H. *The British School of Psychoanalysis: The Independent Tradition*. Yale University Press; 1986; Rodman FR. *Winnicott: Life and Work*. Perseus; 2003	Observed the transitional objects to which a young child becomes attached, which provide a bridge between the child's inner and outer worlds and then influence the development of play, creativity, and cultural life in general; a member of the "independent tradition" in British psychoanalysis (i.e., independent from the views of Klein and Anna Freud), which, instead of emphasizing instincts, stressed object relations
Jean Delay (1907–1987), Pierre Deniker (1917–1999)	France	Delay J, Deniker P. Le traitement des psychoses par une méthode neurolytique dérivée de l'hibernothérapie. *C R Congrés Med Alién Neurol France*. 1952;50:497; Thuillier J. *Ten Years That Changed the Face of Mental Illness*. Martin Dunitz; 1999; Healy D. *The Creation of Psychopharmacology*. Harvard University Press; 2002	In their first reports on chlorpromazine to French psychiatrists, Delay and Deniker emphasized that patients were quieted like animals in hibernation and called the drug "hibernotherapie"; chlorpromazine and related compounds then came into wide general use for treating patients with psychosis and helped to reduce the number of asylum patients
Harry Stack Sullivan (1892–1949)	United States	Sullivan HS. *The Interpersonal Theory of Psychiatry*. Perry HS, Gawel ML, eds. WW Norton; 1953; Perry HS. *Psychiatrist of America: The Life of Harry Stack Sullivan*: The Belknap Press of Harvard University Press; 1982	The interpersonal theory holds that a person's impulses and strivings cannot be studied in and for themselves, but only as they appear in an interpersonal situation; Sullivan also coined the terms *participant observer* (therapists must be aware of the overt and covert behavior of the patient and their own reactions); *consensual validation* (the awareness of patient and therapist of the terminology they use); and *parataxic distortion* (the patient's distortion of the real person of the therapist necessitated by the patient's personality structure)
Egas Moniz (1874–1955), Walter Freeman (1895–1972)	United States, Europe	Valenstein ES. *Great and Desperate Cures: The Rise and Decline of Psychosurgery and Other Radical* Treatments for Mental Illness. Basic Books; 1986; Pressman JD. *Last Resort: Psychosurgery and the Limits of Medicine*. Cambridge University Press; 1998	During the late 1940s and early 1950s, under the influence of Moniz and Freeman, many patients with severe psychoses and OCD were treated by lobotomy—destruction of the white matter of the frontal lobes of the brain; no adequately controlled studies were ever performed; some patients improved, but others experienced irreversible personality deterioration; with the advent of the psychotropic drugs, the use of lobotomies markedly declined
Advent of the double-blind test	United States	Gold H, Kwit NT, Otto H. The xanthines (theobromine and aminophylline) in the treatment of cardiac pain. *JAMA*. 1937;108:2173; Hampson JL, Rosenthal D, Frank J. A comparative study of the effect of mephenesin and placebo on the symptomatology of a mixed group of psychiatric outpatients. *Bull Johns Hopkins Hosp*. 1954;95:170	In the double-blind test, a drug or a procedure and a placebo are compared in such a way that neither the patient nor the therapists involved in treatment know which preparation is being administered; this type of test was first used in medicine in 1937 to evaluate the efficacy of the xanthines in relieving cardiac pain; it was used in psychiatry in 1954 to evaluate the efficacy of mephenesin, and then lithium, in relieving different psychiatric illnesses; since 1954, the main psychiatric use of double-blind tests has been to evaluate the efficacy of psychotropic drugs and psychiatric procedures

Carl Gustav Jung (1875–1961)	Switzerland	*Psychological Types* (1921), *Two Essays on Analytical Psychology* (1912–1928), *The Structure and Dynamics of the Psyche* (1916–1952), *The Archetypes and the Collective Unconscious* (1934–1955); Kirsch T. *The Jungians: A Comparative and Historical Perspective*. Routledge; 2000	After separating from Freud, Jung founded the school of analytical psychology, developing new psychotherapeutic approaches and concepts of the unconscious (especially the collective unconscious) and new personality types, such as introvert and extrovert
Antidepressant drugs	Switzerland, United States	Kuhn R. The treatment of depressive states with an iminodibenzyl derivative (G 22355). *Swiss Med J*. 1957;87:1135; Loomer HP, Saunders JC, Kline NS. A clinical and pharmacodynamic evaluation of iproniazid as a psychic energizer. *Psychiatr Res Rep*. 1957;8:129; Healy D. *The Antidepressant Era*. Harvard University Press; 1997; Kuhn R. *Hist Psychiatry*. 2007;17:253	The first reports of the effectiveness of a tricyclic drug, imipramine (G 22355), and an MAOI, iproniazid (Marsilid), in the treatment of depression
B. F. Skinner (1904–1990), Joseph Wolpe (1915–1997)	United States, South Africa	Skinner BF. *Science and Human Behavior.* Free Press; 1953; Wolpe J. *Psychotherapy by Reciprocal Inhibition*. Stanford University Press; 1958	Skinner's operant conditioning and Wolpe's reciprocal inhibition were important trends in the development of behavioral therapy
Development of child psychiatry	United States	Lewis M, ed. *Child and Adolescent Psychiatry: A Comprehensive Textbook.* 2nd ed. Williams & Wilkins; 1996: Chapters 120 (Rafferty F. Effects of health delivery systems on child and adolescent mental health care); 123 (Schowalter J. Recruitment, training, and certification in child and adolescent psychiatry in the United States); 127 (Bernstein D. The discovery of the child: A historical perspective on child and adolescent psychiatry)	After 1945, child psychiatry developed as a psychiatric specialty that separated from adult psychiatry with the formation of the American Academy of Child Psychiatry (1953) and the American Board of Child Psychiatry (1959)
Karl Jaspers (1883–1969)	Germany	*General Psychopathology* (1st ed., 1913; 7th ed., 1959) (English trans., 1963)	Delineated different mental states to show the meaningful connections between different thoughts (without looking for an underlying cause), and to have empathy for both the felt mental state of the patient and the observing mental state of the physician; this view influenced psychotherapy in general and became part of the tenets of existential psychotherapy
Kurt Schneider (1887–1967)	Germany	Schneider K. *Psychopathic Personalities.* Cassell; 1958; Schneider K. *Clinical Psychopathology*. Grune Stratton; 1959	In clinical psychiatry, Schneider carried forward—with modifications—the descriptive and phenomenologic approaches of Kraepelin and Jaspers; his work included clinical and phenomenologic descriptions of the experience of delusions and hallucinations and a classification and definition of the primary and secondary symptoms of schizophrenia; *Psychopathic Personalities* described a number of abnormal personality types that he encountered in practice and differentiated from psychotic states.
Michel Foucault (1926–1984)	France	*Histoire de la folie* (1961); English trans., *Madness and Civilization: A History of Insanity in the Age of Reason*. Pantheon; 1965	Gave an unconventional history of attitudes toward insanity in Europe from 1500 to 1800; believing that sanity and insanity are largely conditioned by history and the model on which a given society operated, he postulated that creation of the asylum and moral therapy at the end of the 18th century was not progress but an attempt to force insane people to conform to existing social values, and that the authority of the psychiatrist who headed the hospital did not derive from his knowledge of the science of human behavior, but from his association with the power of society; although important historians showed that many of his facts and interpretations contained serious errors, his ideas continue to be debated; *Histoire de la folie* is, in the words of Porter, "easily…the single most influential text of psychiatric historiography in the second half of the century"

Benzodiazepine drugs	United States	Cohen IM. The benzodiazepines. In: Ayd FJ Jr, Blackwell B, eds. *Discoveries in Biological Psychiatry*. Ayd Medical Communications; 1984:130	The benzodiazepines were developed by the pharmaceutical company of Hoffmann-La Roche; chlordiazepoxide (Librium) was first marketed in 1960 and diazepam (Valium) in 1963; the drugs became widely prescribed as anxiolytic drugs in cases of nonpsychotic anxiety
Haloperidol in the treatment of Gilles de la Tourette syndrome	France	Seignot JN. Un cas de maladie des tics de Gilles de la Tourette guéri par le R-1625. Ann Med Psychol. 1961; cxix: 578; The case of Gilles de la Tourette syndrome: A condition of nervous tics cured by R. 1625. *Hist Psychiatry*. 1997;8:434	Reported the cure of one case of Tourette syndrome with haloperidol in 1961, when the drug was an experimental compound (R. 1625); However, the patient treated had previously undergone a lobectomy, which easily could have affected his response; since then, haloperidol has become probably the most commonly prescribed drug for Tourette syndrome
Joint Commission on Mental Illness and Mental Health (1955–1961)	United States	*Action for Mental Health* (1961); Community Mental Health Centers Act of 1963	*Action for Mental Health* recommended psychiatric deinstitutionalization of the care of persons with mental illness by shifting their care from large mental hospitals into community mental health clinics; deinstitutionalization became a reality with the passage of the Community Mental Health Centers Act of 1963
Popular Media	United States	The Myth of Mental Illness, by Thomas Szasz is published.	The book was a powerful critique of contemporary psychiatric practice and is considered a classic.
Rene Spitz (1887–1974)	Europe, then United States	*The First Year of Life: A Psychoanalytic Study of Normal and Deviant Development of Object Relations*. International Universities Press; 1965	Showed that, when separated from their mothers during the first year of life, some infants exhibited overt depression, characterized by *marasmus* (a pining away of a physically healthy child), which could result in death; Spitz also observed that indiscriminate smiling at moving faces and masks began between the ages of 2 and 6 months, and that smiling at familiar faces occurred only after age 6 months
Classification of mental disorders	United States	DSM-I prepared by the Committee on Nomenclature and Statistics of the APA, G.N. Raines, chair (Mental Hospital Service, Washington, DC, 1952); DSM-II prepared by the Committee on Nomenclature and Statistics of the APA, E. Gruenberg, chair (APA, Washington, DC, 1968); Grob G. Origins of DSM-I: A study in appearance and reality. *Am J Psychiatry*. 1991;148:421	DSM-I replaced several outdated classifications of mental disorders and for the first time provided a glossary of definitions of psychiatric conditions; it was not universally accepted in the United States and most other countries; although DSM-II diagnosed new disease entities, including disorders of childhood and adolescence, its diagnostic methods and criteria were criticized by several leading psychiatrists
Epidemiologic evidence for the genetic transmission of schizophrenia	United States, Denmark	Rosenthal D, Kety SS, eds. *The Transmission of Schizophrenia*. Pergamon Press; 1968:235 (Wender PH, Rosenthal D, Kety SS. A psychiatric assessment of the adoptive parents of schizophrenics), 345 (Kety SS, Rosenthal D, Wender PH, Schulsinger F. The types and prevalence of mental illness in the biological and adoptive families of adopted schizophrenics), and 377 (Rosenthal D, Wender PH, Kety SS, Schulsinger F, Welner J. Schizophrenics' offspring reared in adoptive homes); Kety SS, Wender PH, Jacobsen B, Ingraham LJ, Jansson L. Mental illness in the biological and adoptive relatives of schizophrenic adoptees: Replication of the Copenhagen study in the rest of Denmark. *Arch Gen Psychiatry*. 1994;51:442	A study of 5,483 Danish adoptees found that 507 had been admitted to a psychiatric hospital, and 33 were classified as having schizophrenic disorders; an equal number of matched adoptees who had no history of psychiatric disorders were identified for comparison; of the 150 biologic relatives of the schizophrenic adoptees, 8.7% had a diagnosis of schizophrenia, compared with 1.9% of the 156 biologic relatives of the nonschizophrenic adoptees; that significant difference indicated that genetic factors were important in the transmission of schizophrenia; these statistics were then replicated by statistics from the rest of Denmark; this method of study was later used to show that other psychiatric disorders (bipolar disorder, suicide, psychopathy, felonious behavior, alcoholism, and hyperactivity in children) were caused by genetic factors; it stimulated molecular geneticists to search for the molecular genetic basis of those disorders
Lithium therapy for psychotic excitement	Australia, Denmark, United States	Cade J. Lithium salts in the treatment of psychotic excitement. *Med J Aust*. 1949;36:349; Schou M, Juel-Nielsen N, Stromgren E, Voldby H. The treatment of manic psychoses by the administration of lithium salts. *J Neurol Neurosurg Psychiatry*. 1954;17:250; Schou M. Forty years of lithium treatment. Arch Gen Psychiatry. 1997;54:9; J Schioldann: Mogens Abelin Schou (1918–2005)—Half a century with Lithium. *Hist Psychiatry*. 2007;17:247	After the Australian psychiatrist Cade reported that lithium quieted manic patients, the Danish psychiatrist Schou confirmed that finding in a double-blind study; Schou then developed lithium therapy for manic-depressive illness; because of lithium's toxicity and because many psychiatrists questioned its therapeutic effectiveness, it was not approved until 1970 by the U.S. Food and Drug Administration

William H. Masters (1915–2001), Virginia E. Johnson (1925–)	United States	*Human Sexual Response* (1966), *Human Sexual Dysfunction* (1970)	Both books revolutionized knowledge and attitudes about sex; *Response* showed that the female capacity for orgasm greatly exceeds that of most men, that Freud's theories of clitoral and vaginal orgasm needed revision, and that the capacity for meaningful sexual relationships continues into old age; *Dysfunction* stated that most sexual dysfunctions are amenable to some form of counseling; although that statement needed further verification, it gave hope to patients and sex counselors, and it stimulated the discipline of sex therapy
Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United States	Kenneth Clark becomes first African-American president of the APA in 1966.	
Margaret Mahler (1897–1985)	Central Europe until 1938, then United States	Mahler M, Pine F, Bergman A. *The Psychological Birth of the Human Infant: Symbiosis and Individuation*. Basic Books; 1975; *The Memoirs of Margaret S. Mahler*. Stepansky PE, ed. Free Press; 1988	Delineated the series of stages marking the infant's gradual intrapsychic separation from the mother and its understanding of itself as a distinct individual along with other equally distinct individuals
John Bowlby (1907–1990)	England	*Attachment* (1969), *Separation: Anxiety and Anger* (1973), *Loss: Sadness and Depression* (1980), *A Secure Base: Clinical Applications of Attachment Theory* (1988); *Holmes J. John Bowlby and Attachment Theory*. Routledge; 1993	Bowlby's attachment theory is largely based on the belief that a child's social and emotional development depends on the formation, maintenance, and renewal of attachment and affection as bonds between a child and parent (caregiver); deviant emotional and personality development is attributed to the rejection or disruption of ambivalent attachment bonds; loss, or threat of loss, of the attachment figure is viewed as a principal pathogenic agent; Bowlby furthermore believed that when the attachment behaviors of the child are nurtured by the caregiver, the child can develop a sense of security that then allows safe exploration of the world (environment), a positive sense of self, and good relations with others
Jacques Lacan (1901–1981), "the French Freud"	France	*The Language of the Self: The Function of Language in Psychoanalysis* (1968); *Turkle S. Psychoanalytic Politics: Freud's French Revolution*. Basic Books; 1978; Roudinesco E. Jacques Lacan & Co.: *A History of Psychoanalysis in France, 1925–1985*. University of Chicago Press; 1990	Emphasized language and the need to make contact with the prelanguage period in the unconscious and rejected the standard 50-minute analysis for sessions that were sometimes 10, 5, or even 3 minutes; founded a school of psychoanalysis, described as a return to Freud; at the time of his death, there were reportedly 5,000 Lacanian analysts in France; the most influential figure in French psychiatry; his ideas influenced literature, language, linguistics, economics, and mathematics; he was an integral part of the political left
Heinz Kohut (1913–1981)	Austria until 1940, then United States	*The Analysis of the Self* (1971); *The Restoration of the Self* (1977); The two analyses of Mr. Z. *Int J Psychoanal*. 1979;60:3; Baker H, Baker M. Heinz Kohut's self psychology: An overview. *Am J Psychiatry*. 1987;144:1; Strozier CS. Heinz Kohut: *The Making of a Psychoanalyst*. Farrar, Straus and Giroux; 2001	Originated the psychoanalytic school of self-psychology, which delineated a new group of developmental needs and three new views of transferences: Mirroring, idealizing, and alter ego
Jean Piaget (1896–1980)	Switzerland	Greenspan, Curry J. Piaget's approach to intellectual functioning. In: Kaplan HI, Sadock BJ, eds. *Comprehensive Textbook of Psychiatry*. 6th ed. Williams & Wilkins; 1995	Influenced by his observations of his three children, Piaget found four major stages in the formation of thought from infancy through adolescence, with each a necessary prerequisite for the one that follows: (1) *sensorimotor* (up to 2 years), child learns about space and permanent objects; (2) *preoperational* (2–7 years), verbal symbols are learned so words come to represent objects; (3) *concrete operations* (7–11 years), objects become classified according to similarities; (4) *formal operations* (11 years through end of adolescence), adult logical thinking is used more and more; although there have been criticisms and revisions of these four stages, they will (in the words of Greenspan and Curry) "serve as a basis for understanding social and emotional development and provide a framework for clinical and educational intervention"

Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United States	The Caucus of Gay, Lesbian, and Bisexual Members of the APA is founded in 1975.	The group quickly became an important advocacy group for LGBT mental health issues. In 1985 they changed their name to the Association of Gay and Lesbian Psychiatrists.
NAMI	United States	NAMI: *We Are Family*. Arlington, VA: NAMI; 1979; a 10-page brochure describing the work of NAMI; since then NAMI has published regular annual reports on its work	NAMI, founded in 1979 as an organization of patients with schizophrenia and their family members, has developed new approaches to working with families—counseling, individual family therapy, multifamily therapy groups, and psychoeducational programs—and is probably the most vigorous citizens' group in America that advocates to legislators and the public for the problems of persons with mental illness
Classification of mental disorders / Diversity, Equity, Inclusion, and Justice	United States	Transgender people are classified by the APA as having Gender Identity Disorder	
Sociobiologic psychiatry	United States, Holland	Van Praag H. Sociobiological psychiatry. *Compr Psychiatry*. 1981;22:441	An approach to the treatment of mental illnesses developed by the Dutch psychiatrist Herman van Praag; it analyzes the possibilities and limitations of pharmacotherapy and psychotherapy and their compatibility when used together in the treatment of psychiatric patients in various diagnostic categories
Roger Sperry (1913–1994)	United States	Some effects of disconnecting the cerebral hemispheres. *Science*. 1982;217:1223; Sperry RW, Levi-Montalcini R. In: Finger S, ed. *Minds Behind the Brain: A History of the Pioneers and Their Discoveries*. Oxford University Press; 2000	In 1981, Sperry shared the Nobel Prize in Physiology or Medicine for his work demonstrating that the left brain hemisphere contains the primary speech capacity, that the right hemisphere is involved with short-term memory, and that the two function independently when the connection between them is cut; this work (funded by grants from the NIMH) suggested that such states as autism and delusions sometimes may be caused by disturbances in the connections between the hemispheres
Brief psychotherapy	United States, England	Malan D. *A Study of Brief Psychotherapy*. Plenum Press; 1976; Mann J, Goldman R. *A Casebook in Time-Limited Psychotherapy*. McGraw-Hill; 1982; Davanloo H. *Short-Term Dynamic Psychotherapy*. Jason Aronson; 1980; Sifneos P. *Short-Term Dynamic Psychotherapy Evaluation and Technique*. Plenum Press; 1979; Crits-Cristoph P. The efficacy of brief dynamic psychotherapy: A meta-analysis. *Am J Psychiatry*. 1992; 149:151	Aims at producing insight and personality changes in a patient in a short, cost-limited time frame; it includes limiting time devoted to therapy, focusing on a particular problem, actively involving the therapist, engaging in anxiety-provoking confrontations, past–present link interpretations, and problem solving, recapitulating patient's resistances, emphasizing change and progress, and terminating early
Psychology of women	United States	Miller JB. *Towards a New Psychology of Women*. Beacon Press; 1976; Gilligan C. *In a Different Voice: Psychological Theory and Women's Development*. Harvard University Press; 1982; Levinson D, in collaboration with Levinson J. *The Seasons of a Woman's Life*. Knopf; 1996	Jean Baker Miller, Carol Gilligan, and Daniel Levinson offer different views on women's psychology and the female life cycle
Mental Health Policy		President Bill Clinton signs the Mental Health Parity Act	This act is later amended by President George W Bush in 2008 to close loopholes.
NARSAD	United States	NARSAD activities are reported in *Research* brochures and *Newsletters*	NARSAD was organized in 1986; in 1987, a funding program with 10 grants of $25,000 each was instituted; in 2003, NARSAD reported that in 15 years, it had awarded $144.4 million to fund 2,153 grants to 1,711 scientists at 312 universities and medical research institutions for research in schizophrenia and depression; in 2007 NARSAD announced that it had awarded 23 Distinguished Investigator grants and 222 Young Investigator grants; it has become the largest nongovernment, publicly funded organization that distributes funds for brain disorder research

Changes in the diagnosis and classification of homosexuality	United States	Bayer R. *Homosexuality and American Psychiatry: The Politics of Diagnosis*. Basic Books; 1981; DSM-III (1980); DSM-III-R (1987)	In 1973, in the light of new clinical information and under political pressure from the National Gay Task Force, the APA changed its diagnosis of homosexuality from a disease to a condition that can be considered a disease only if it is subjectively disturbing to the person; although some APA members protested the decision, it was upheld in a 1974 APA referendum; in the DSM-III, homosexuality was diagnosed as *ego-dystonic homosexuality;* in DSM-III-R, the reference to homosexuality was eliminated; some of the factors that influence a person to have a homosexual orientation are known (biology, family cultural environment, intrapsychic psychodynamics), but others remain unknown
Classification of mental disorders	United States	DSM-III (1980); DSM-III-R (1987); Wilson M. DSM-III and the transformation of American psychiatry: A history. *Am J Psychiatry*. 1993;150:399	The DSM-III-R reorganized the entire system of classifying diseases, leading to a more detailed, precise, and clear delineation of symptoms and a more medical and less psychoanalytic view of the symptoms; it was widely read and accepted in the United States and became the common language used by workers in psychiatry; the DSM-III-R was published because data from new studies were inconsistent with some of the previous diagnostic criteria and because of the need to review the criteria (along with systematic descriptions of diseases) for clarity and conceptual accuracy
Organizational Psychiatry	Europe	European Psychiatric Association founded in 1983	
Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United States	Carol Nadelson becomes first woman president of the APA in 1984.	
James Masterson (1926–), Otto Kernberg (1928–)	United States	Masterson J. *Psychotherapy of the Borderline Adult: A Developmental Approach*. Brunner/Mazel; 1976; *Narcissistic and Borderline Disorders: An Integrated Developmental*. Brunner/Mazel; 1981; Masterson J, Klein R, eds. *Psychotherapy of the Disorders of the Self: The Masterson Approach*. Brunner/Mazel; 1988; Kernberg O. *Borderline Conditions and Pathological Narcissism*. Jason Aronson; 1975; Kernberg O. *Severe Personality Disorders: Psychotherapeutic Strategies*. Yale University Press; 1984	Masterson and Kernberg developed two different psychoanalytic concepts (both emphasizing object relations) for understanding, diagnosing, and treating narcissistic and borderline personality disorders
Psychology and neurophysiology of dreams	United States	Hobson JA, McCarley RW. The brain as a dream state generator: An activation-synthesis hypothesis of one dream process. *Am J Psychiatry*. 1977;134:1335; McCarley RW. Dreams: Disguise of forbidden wishes or transparent reflections of a distinct brain state? In: Bilder RM, Lefever FF, eds. *Neuroscience of the Mind: On the Centennial of Freud's Project for a Scientific Psychology*. New York Academy of Sciences; 1998:116; Reiser MF. The dream in contemporary psychiatry. *Am J* Psychiatry. 2001;158:351	The Hobson–McCarley activation–synthesis hypothesis of dream formation, based on neurophysiologic research, postulates that dreams are caused by two reciprocally interacting groups of brainstem neurons; although this hypothesis at first tended to view dreams as products of brain physiology that lacked intrinsic psychological importance (and thus refuted Freud's psychoanalytic theory of dreams), this view has lately changed; Reiser suggested that new research has shown that the psychology of dreams is more complex than has been previously thought and postulated "a preliminary psychobiological concept of the dream process" in which "the mind exploits (for memory and cognitive functions) the special physiologic state of the activated dreaming brain"; Reiser emphasized that this concept is not a "final or complete understanding of the dream process," but that it may serve as a stimulus "for further research to both psychoanalysis and cognitive neuroscience"

Theories on the psychology of love	United States	Bergmann MS. *The Anatomy of Loving*. Columbia University Press; 1987; Sternberg RJ. *The Triangle of Love: Intimacy, Passion, Commitment*. Basic Books; 1987; Sternberg RJ, Barnes ML, eds. *The Psychology of Love*. Yale University Press; 1988; Gaylin W, Person E, eds. Passionate *Attachments: Thinking about Love*. Free Press; 1988; Person E. *Dreams of Love and Fateful Encounters: The Power of Romantic Passion*. WW Norton; 1988	These books, which appeared within 1 year of one another, differed in their accounts of the nature of love; no one dominant theory emerged, yet each book offered new information and ideas on the phenomenology of love
Evaluations of psychotherapy	United States	Bruce R, Staples FR, Cristol AH, Yorkston NJ, Whipple KS. *Psychotherapy versus Behavior Therapy*. Harvard University Press; 1975; Elkin I, Shea MT, Watkins JT, Imber SD, Sotsky SM. National Institute of Mental Health Treatment of Depression Collaborative Research Program: General effectiveness of treatments. *Arch Gen Psychiatry*. 1989;48:971	Two methodologically sophisticated studies that concluded that groups of neurotic patients in psychotherapy showed a significant reduction in their symptoms when compared with control groups
Eric Kandel (1929–)	Austria, United States after 1939	Kandel E. Psychotherapy and the single synapse: The impact of psychiatric neurobiological research. *N Engl J Med*. 1979;301:1028; From metapsychology to molecular biology: Explorations into the nature of anxiety. *Am J Psychiatry*. 1983;140:1277; Genes, nerve cells, and the remembrance of things past. J Neuropsychiatry. 1989;1:103; Biology and the future of psychoanalysis: A new intellectual framework for psychiatry revisited. *Am J Psychiatry*. 1999;156:505; *In Search of Memory: The Emergence of a New Science of Mind*. WW Norton; 2006	Showed connections between psychiatry and neurobiology and research on the CNS of the snail *Aplysia;* developed an experimental system and set of conceptual approaches for studying the biologic basis of simple forms of learning and memory and demonstrated that "learning produces changes in neuronal architecture, changes that result from learned alterations in gene expression"; suggested that normal learning, learning of neurotic behavioral patterns, and unlearning of such detrimental behaviors through psychotherapeutic intervention might involve long-term functional and structural changes in the brain that result from altered gene expression; in his 1999 article, Kandel suggested ways of creating a discipline of neurobiology, cognitive psychology, and psychoanalysis that "would forge a new and deeper understanding of the mind" In 2000, the Nobel Prize for Physiology or Medicine was awarded to three men: Kandel for work in *Aplysia* (the second psychiatrist to receive the prize, after Wagner von Jauregg); Arvid Carlsson, a neuropsychopharmacologist at the University of Gothenburg in Sweden, known for his development of the dopamine hypothesis; and Paul Greengard, a neuroscientist at Rockefeller University in New York City, who studied how such neurotransmitters as dopamine communicate their signals at the cellular level. (Andreasen NC. Three living heroes of contemporary psychiatry. *Am J Psychiatry*. 2000;157:1911)
Aaron Beck (1921–)	United States	Beck A. *Cognitive Therapy and the Emotional Disorders*. International Universities Press; 1976; Beck A, Rush AJ, Shaw BF, Emery G. *Cognitive Therapy of Depression*. Guilford Press; 1979; Beck A, Emery G, Greenberg R. *Anxiety Disorders and Phobias: A Cognitive Perspective*. Basic Books; 1985; Beck A, Freeman A. *Cognitive Therapy of Personality Disorders*. Guilford Press; 1990; Weishaar M. Aaron T. Beck. *Key Figures in Counselling and Psychotherapy*. Sage; 1993; Barsky AJ, Ahern DK. Cognitive behavioral therapy for hypochondriasis. A randomized controlled trial. *JAMA*. 2004;291:1464	As formulated by Beck, cognitive therapy is a system of psychotherapy based on a theory of psychopathology and a set of therapeutic principles and techniques that emphasize the reorganization of a person's maladaptive processes of perceiving, thinking, and forming opinions; the study of Barsky and Ahern showed that cognitive-behavioral therapy in six 90-minute intervals "appears to have significant beneficial long-term effects on the symptoms of hypochondriasis." On November 16, 2007 Beck was one of five scientists chosen to receive the Lasker Award for his technique of cognitive therapy; the Award is considered the nation's most prestigious medical awards and carries a prize of $100,000. (*The New York Times*, November 17, 2007, Section N, p. 24)

Karl Menninger (1893–1990), William Menninger (1900–1966)	United States	Faulkner H, Pruitt V, eds. *The Selected Correspondence of Karl A. Menninger*. Yale University Press; 1988; Friedman LJ. *Menninger: The Family and the Clinic*. Knopf; 1990	The Menninger Clinic (founded in 1920 in Topeka, Kansas) became recognized for its innovative approaches to mental health, scientific excellence, and emphasis on public service; William Menninger introduced new, effective treatments for American psychiatric casualties in World War II; Karl Menninger applied psychoanalytic concepts to American psychiatry and wrote three popular and influential psychiatric-psychoanalytic books: *The Human Mind* (1930), *Man Against Himself* (1938), and *Love Against Hate* (1942); in June 2003, the Clinic moved from Topeka to Houston, Texas, where it became partners with Baylor College of Medicine and the Methodist Hospital
Frederick K. Goodwin (1936–), Kay Redfield Jamison (1946–)	United States	Goodwin FK, Jamison KR. *Manic-Depressive Illness*. Oxford University Press; 1990; 2nd ed., 2007	Offered a new diagnosis and classification of manic-depressive illness as a cluster of related illnesses, including bipolar disease, cyclothymia, and recurrent depressive disease; also offered the most comprehensive review of all information on the disease and all aspects of treatment, including medical (acute and prophylactic) and the role of psychotherapy
A memoir of depression	United States	Styron W. *Darkness Visible: A Memoir of Madness*. Random House; 1990	A national bestseller, described by the *Washington Post* as "a striking addition to the notable personal accounts of mental illness"; has been used by therapists as "an invaluable document" to help patients understand the symptoms of their depression. (*The New York Times,* November 12, 2006, Section 4, p. 11)
SSRIs	United States	"The Story of Prozac," Pharmaceutical Manufacturers Association; 1993; Grebb J. Serotonin-specific inhibitors. In: Kaplan HI, Sadock BJ, eds. *Comprehensive Textbook of Psychiatry*. 6th ed. Williams & Wilkins; 1995	SSRIs are antidepressants, generally as effective as previous antidepressants but with fewer adverse effects; the first SSRI, fluoxetine (Prozac), developed by Lilly in the 1970s, has become the most widely prescribed antidepressant in the United States; it was followed by sertraline (Zoloft), developed by Roerig in 1992, and paroxetine (Paxil), developed by SmithKline Beecham in 1993
Jerome Frank (1910–2005), E. Fuller Torrey (1937–)	United States	Frank J. *Persuasion and Healing: A Comparative Study of Psychotherapy*. Johns Hopkins University Press; 1961; 2nd rev. ed., 1973; Frank J, Frank JB. *Persuasion and Healing: A Comparative Study of Psychotherapy*. 3rd rev. ed. Johns Hopkins University Press; 1991; Torrey EF. *The Mind Game: Witchdoctors and Psychiatrists*. Emerson Hall; 1972; Torrey EF: *Witchdoctors and Psychiatrists: The Common Roots of Psychotherapy and Its Future*. Harper & Row; 1986 (a revised edition of *The Mind Game*)	These books offered perspectives on the practices of contemporary American psychotherapy and psychotherapists by delineating how psychic changes are effected in a wide range of therapist–patient interactions, including miracle cures, faith healing, Communist thought control, the so-called placebo effect in medicine, special types of individual and group psychotherapies, and the work of traditional healers in third-world countries and among Mexican and Puerto Rican Americans and Navaho
Neuroimaging	United States	Kenneth Kwong publishes his pioneering work in functional brain imaging in 1992	
Psychiatric epidemiology	United States	Robins LN, Regier DA, eds. *Psychiatric Disorders in America: The Epidemiologic Catchment Area Study*. Free Press; 1991	This NIMH Epidemiologic Catchment Area study, the largest and most sophisticated study of psychiatric epidemiology ever undertaken in the United States, showed that more than 30% of individuals have at least one psychiatric disorder (and many have more than one); that alcoholism and phobic disorder are the most common illnesses, followed by depression; that the uneducated, unmarried, and divorced are more vulnerable; that, more important than race or economic status as a predictor of most illness, the young are more vulnerable than their elders; the study permitted follow-up and evaluation of changes (both overall and in specific areas) to show how particular services are used or not used; it thus continues to provide data for an ongoing discussion of mental health needs and future psychiatric research projects

Forensic psychiatry	United States	Bursztajn H, Scherr A, Brodsky A. The rebirth of forensic psychiatry in light of recent historical trends in criminal responsibility. *Psychiatr Clin North Am*. 1994;1(3):611; Prentice S. A history of subspecialization in forensic psychiatry. *Bull Am Acad Psychiatry Law*. 1995;23(2):195	Changing concepts of criminal responsibility in mid-20th century America, and interactions between the American Academy of Forensic Sciences and the American Academy of Psychiatry and the Law, resulted in forensic psychiatry's becoming officially recognized as a subspecialty by the American Board of Medical Specialties on September 17, 1992, under the designation of "Added Qualification in Forensic Psychiatry"
Epidemic of AIDS and of persons infected with HIV (1981–)	Worldwide	Grmek M. *History of AIDS: Emergence and Origin of a Modern Pandemic*. Princeton University Press; 1990; Berridge V, Strong P, eds. *AIDS and Contemporary History*. Cambridge University Press; 1993; Feldman D, Miller J, eds. *The AIDS Crisis: A Documentary History*. Greenwood Press; 1998; Bayer R, Oppenheimer G, eds. *AIDS Doctors: Voices from the Epidemic*. Oxford University Press; 2000; Treisman G, Angelino F. *The Psychiatry of AIDS: A Guide to Diagnosis and Treatment*. Johns Hopkins University Press; 2004; Mayer K, Pizer H, eds. *The AIDS Pandemic: Impact on Science and Society*. Elsevier Academic Press; 2005	Psychiatrists are called on to manage individuals who are at high risk for HIV infection or who are HIV infected and to treat the psychiatric disorders that result from or are comorbid with HIV infection; these disorders include dementia, delirium, anxiety, and disorders of cognition, adjustment, mood, and sleep; because AIDS is largely caused by sexual contact and IV drug use, psychiatrists and mental health professionals need to teach the techniques of safe sex and safe drug use and work with addicts to withdraw from drug; the global incidence of AIDS is steadily increasing
Classification of mental disorders	United States	*American Psychiatric Association: Diagnostic and Statistical Manual of Mental Disorders*. 4th ed. Text rev. American Psychiatric Association; 2000 (DSM-IV-TR)	The DSM-IV, probably the most ambitious undertaking in the history of American psychiatric nosography, was based on 6 years of collecting and analyzing relevant information and making field tests of proposed changes in diagnosis; it continued the atheoretical approach to causes, made fewer diagnostic changes than the DSM-III, systematically described each disorder in terms of its associated features, and replaced the DSM-III-R as the diagnostic text used by workers in psychiatry; the DSM-IV-TR contained updated information about the associated features, prevalence, course, and familial pattern of some of the mental disorders that had been described in the DSM-IV; it also gave more comprehensive diagnostic criteria for personality change due to a general medical condition, paraphilias, and tic disorders than those given in the DSM-IV
Clozapine, risperidone, and olanzapine in the treatment of schizophrenia	United States, Canada, Europe, England, South America, South Africa	Kane J, Honigfield G, Singer J, Meltzer H, and the Clozaril Collaborative Study Group: Clozapine for the treatment-resistant schizophrenic. A double-blind comparison with chlorpromazine. *Arch Gen Psychiatry*. 1988;45:789; Kane J, Marder SR. Clozapine benefits and risks. *Schizophren Bull*. 1994;20:23; Ayd FJ Jr. Risperidone (Risperdal): A unique antipsychotic. *Int Drug Ther Newslett*. 1994;29:5; Marder SR, Meibach RC. Risperidone in the treatment of schizophrenia. *Am J Psychiatry*. 1994;151:825; Kane J. Risperidone. *Am J Psychiatry*. 1994;151:802; Beasley C, Tollefson G, Tran P, Satterlee W, Sanger T. Olanzapine versus placebo and haloperidol acute phase results of the North American double-blind olanzapine trial. *Neuropsychopharmacology*. 1996;14:111; Tollefson G, Kuntz A. Review of recent clinical studies with olanzapine. *Br J Psychiatry*. 1999;37:30; Volavka J, Czobor P, Sheitman B, Lindenmayer JP, Citrome L. Clozapine, olanzapine, risperidone, and haloperidol in the treatment of patients with chronic schizophrenia and schizoaffective disorder. *Am J Psychiatry*. 2002;159:255; Grilly J. The history of clozapine and its emergence in the U.S. market: A review and analysis. *Hist Psychiatry*. 2007;18:39	Clozapine and risperidone have been used successfully since 1989 and 1994 to treat both positive and negative schizophrenic symptoms that have been resistant to other treatments; these drugs each offer the possibility for real and continued improvement of individuals who are persistently psychotic; olanzapine has been in use since September 1996 and is effective in treating positive and negative schizophrenic symptoms; the 2002 study by Volavka et al. on 157 hospital in-patients who had a diagnosis of chronic schizophrenia or schizoaffective disorder showed that clozapine, risperidone, and olanzapine (but not haloperidol) resulted in statistically significant improvements in the positive and negative symptoms of hospital patients: "The overall pattern of results suggests that clozapine and olanzapine have similar general antipsychotic efficacy and that risperidone may be somewhat less effective. Clozapine was the most effective in treatment for negative symptoms. However, the differences were small."

Publications in psychohistory and psychobiography	United States, England	Lawton H. *The Psychohistorian's Handbook*. Psychohistory Press; 1988; Elovitz P, ed. Clio's Psyche. Understanding the "Why" of Culture, Current Events, History, and Society (1994) (a quarterly periodical published by the Psychohistory Forum, 627 Dakota Trail, Franklin Lakes, NJ 07417); Sabbadini A, ed. Psychoanalysis and History. Vol. 1, No. 1. Artesian Books; 1998–1999 (since its first issue, this *History* has appeared at regular intervals of twice a year; since 2005 edited by John Forrester, and since 2007 published by Edinburgh University Press); Szaluta J. *Psychohistory: Theory and Practice*. Peter Lang; 1999; Elovitz P. Psychoanalytic scholarship on American Presidents. *Annu Psychoanal.* 2003;31:135; Schultz WT, ed. *Handbook of Psychohistory*. Oxford University Press; 2005	Lawton defined *psychohistory* "as the interdisciplinary study of why man has acted as he has in history, prominently utilizing psychoanalytic principles" (no uniformly accepted definition exists); examined different psychohistorical writings, concepts, and methods of doing interdisciplinary research (most of which date from the appearance of Erikson's *Young Man Luther* in 1958); and called attention to the two best-established journals in the field, started in the 1970s: the *Psychohistory Review* (stopped publication in 1999) and the *Journal of Psychohistory; Clio's Psyche* has short, concise studies by various authors on greatly varied subjects (including the personalities of famous individuals, presidential character, nationalism, ethnic conflicts and the Holocaust, AIDS, movies, psychological issues, psychoeconomics, and the environment); many studies aim to combine primary research with psychological insights; notable interviews with distinguished psychohistorians (in his interview with *Clio,* psychohistorian Peter Loewenberg commented, "I'd like to get away from the idea of applying psychoanalysis to history because I think the integration of psychodynamic perceptions with historical conceptualization should take place at the moment that the historian contacts the data or the archives. Both history and psychoanalysis are fundamentally historical enterprises—they're models of explanation.") *Psychoanalysis and History* has two stated aims: (1) "historiographic studies of the psychoanalytic movement itself, as well as biographical research on aspects of the lives and works of prominent psychoanalysts. Only one century old, psychoanalysis has an already rich and articulated history, having undergone complex external and internal vicissitudes and having developed its identity in most diverse ways in different geographical regions. We intend … to present as yet unpublished documents … which will throw new light on a number of important aspects of our discipline" and (2) "We shall also attempt to apply psychoanalytic ideas—for instance the concept of unconscious processes, of developmental stages, or of relevant defence mechanisms such as repression, splitting, projective identification and 'deferred action' (Nachtraglichkeit)—to the interpretation of historical events" Szaluta's book was the first text to present both the theory and practice of psychohistory; the contributions of Freud and post-Freudians were delineated, the pros and cons of psychohistory examined, and major works of psychohistory discussed; Szaluta emphasized how psychohistory differs from traditional history and how it can be insightful in the study of the individual, the family, and the group Elovitz discussed how, in almost three decades of research on presidential psychobiography, he was influenced by psychoanalysis to develop a method of "disciplined subjectivity" in which he applied the "nonjudgmental manner of the clinician … to the politician"; he studied his subject's childhood, personality, family background, life crises, defense mechanisms, and patterns of success and failure; throughout the entire process, he carefully monitored countertransference feelings; as a result of following this method, he claimed to understand both the pressures of office and the personalities of presidents and to have insights into "understanding the contradictory desires, the ambivalence, of both the leader and the led" A *Handbook of Psychohistory* offers articles on psychohistory and psychobiography that show a variety of different psychological approaches

Paul Wender (1934–)	United States	*Attention-Deficit Hyperactivity Disorder in Adults*. Oxford University Press; 1998	As a result of his 25 years of studying ADHD in adults, Wender gave new evidence suggesting that ADHD is genetically transmitted and that approximately one-third of children with ADHD reach adulthood with persisting symptoms of the disorder; he also reviewed what was known about ADHD's symptoms, its life course, and the value of treatments with various drugs
Computers and the Internet	United States	The APA has published two books on the use of computers in psychiatry: *Lieff J. Computer Applications in Psychiatry*. American Psychiatric Publishing; 1987; and Chan CH, Luo JS, Kennedy RS. *Concise Guide to Computers in Clinical Psychiatry*. American Psychiatric Publishing; 2002; Miller MJ. Computer-based testing of the psychiatric patient. In: Sadock BJ, Sadock VA. *Comprehensive Textbook of Psychiatry*. 7th ed. Lippincott Williams & Wilkins; 2000	Computers have been applied to practically every area of psychiatry, including recording patient symptoms, facilitating the transfer of records, tracking patients in the community, and establishing databases; they have been used by insurance companies and managed care companies for accounting and monitoring patient care, and, since the 1970s, they have been used with increasing frequency in giving patients psychological tests
		Two articles about the Internet are Alessi NE. The Internet and the future of psychiatry. *Am J Psychiatry*. 1996;153:861; and Rajendran PR. The Internet: Ushering in a new era of medicine. *JAMA*. 2001;285:804	The Internet is a computer communication network that transmits information quickly and easily on a global scale, facilitating contacts between different psychiatrists, and between psychiatrists and patients, and enabling patients to obtain rapid information on the professional qualifications of the psychiatrist who is treating them and the psychiatric medications the psychiatrist has prescribed for them Although the Internet has given new information to persons who previously had not been able to obtain this information, it is information that sometimes needs to be used with caution because it can be the result of covert advertising by individuals or companies and has not been scientifically evaluated
Discoveries of genetic variations as causes of mental illnesses	United States, Canada, England, Europe, Australia	Oberlé I, Rousseau F, Heitz D, Kretz G, Davys D. Instability of a 550–base pair DNA segment in fragile X syndrome. *Science*. 1991;252:1097; Yu S, Pritchard M, Kremer E, Lynch M, Nancarrow J. Fragile X genotype characterized by an unstable region of DNA. *Science*. 1991;252:1179; Ying-Hui Fu, Kuhl DPA, Pizzuti A, Pieretti M, Sutcliffe JS. Variation of the CGG repeat at the fragile X site results in genetic instability: Resolution of the Sherman paradox. *Cell*. 1991;67:1047; Schellenberg GD, Bird TD, Wijsman EM, Orr T, Anderson L. Genetic linkage of evidence for a familial Alzheimer's disease locus on chromosome 14. *Science*. 1992;258:668; Mullen M, Houlden H, Windelspecht M, Fidani L, Lombardi C. A locus for familial early-onset of Alzheimer's disease on the long arm of chromosome 14, proximal to the α-1-antichymotrypsin gene. *Nat Genet*. 1992;2:340; The Huntington's Disease Collaborative Research Group: A novel gene containing a trinucleotide repeat that is expanded and unstable on Huntington's disease chromosome. *Cell*. 1993;72:971; Amir RE, Van den Veyver IB, Wan M, Tran CQ, Franke U. Rett syndrome is caused by mutations in X-linked MECP2, encoding methyl-CpG-binding protein 2. *Nat Genet*. 1999;23:185	During 1991–1993, genetic variations were identified as causes for the fragile X syndrome, a common cause of inherited mental retardation; familial early onset of Alzheimer disease; and Huntington disease; in 1999, it was discovered that the MECP2 gene causes Rett syndrome, a pervasive developmental disorder included in the DSM-IV classification

		Hyman S, Moldin S. Genetic science and depression: Implications for research and treatment. In: Weissman MM, ed. *Treatment of Depression: Bridging the 21st Century*. American Psychiatric Association; 2001:98; Andreasen NC. Schizophrenia. Chapter 8. In: *Brave New Brain: Conquering Mental Illness in the Era of the Genome*. Oxford University Press; 2001:199	The 2001 article by Hyman and Moldin stated that, although previous studies had shown that heredity plays a role in the transmission of depression, "a single major gene is an unlikely contributor to etiology; rather, multiple genes of small effect contribute with nongenetic factors in producing vulnerability to the illness"; in the same year, Andreasen observed, "Most experts now think that schizophrenia is clearly multifactorial, involving multiple genes, and possibly even different genes in different individuals, as well as many nongenetic or environmental influences. The fact that multiple genes are probably involved is the main reason why the various reports that 'the schizophrenia gene has been found on chromosome 5' (or 11 or 22 or elsewhere) have not been consistently repeated"
Three books on psychotherapy	United States	Jackson SW. *Care of the Psyche: A History of Psychological Healing*. Yale University Press; 1999; Sabo AN, Havens L, eds. *The Real World Guide to Psychotherapy Practice*. Harvard University Press; 2000; Hersen M, Sledge WH, eds. *Encyclopedia of Psychotherapy*. 2 Vols. Academic Press; 2002	Jackson's *History* is notable for its delineation of the roles of healer and sufferer throughout history; the essays by Sabo, Havens, and others suggest how, through forming relationships with patients, it is possible to do some effective psychotherapy and to counter the constraints of managed care; the *Encyclopedia* gives concise articles, written by experts, on the major psychotherapies that are now in use, along with studies of the efficacy of each of these therapies
Education of psychiatrists	United States	Luhrmann TM. *Of Two Minds: The Growing Disorder in American Psychiatry*. Knopf; 2000	Depicts contemporary American psychiatry as divided between two views of mental illness: A biomedical model, consisting of symptoms treated by psychopharmacology, and a psychodynamic model, consisting of emotional conflicts, treated by psychotherapy; although Luhrmann states that the use of both models together is necessary in treating patients, she observes that "a combination of socio-economic forces [managed care] and ideology is driving psychotherapy out of psychiatry"; she also observes that this would be bad for psychiatrists and patients and encourages "a way of thinking about mental illness that can strip humanity from its sufferers"
Theory and treatment of depression	United States, England, Switzerland	In a March 1999 New York City meeting of the American Psychopathological Association, leading clinical scientists gave papers on the topic Treatment of Depression, all of which were published as in Weissman MM, ed. *Treatment of Depression: Bridging the 21st Century*. American Psychiatric Association; 2001	The papers ranged widely in discussing different aspects of depression; Charles Nemeroff and Michael Owens, in "Contribution of modern neuroscience to developing new treatments for psychiatric disorders," reviewed the evidence that CRF is hypersecreted in depressed patients, that "untoward early life experience is associated with a persistent CRF gene expression and CRF neuronal activity, which may underlie the vulnerability of individuals exposed to child abuse or neglect to develop depression in adulthood," and that the recent use of a CRF antagonist for the treatment of major depression has been successful; Steven Hyman and Steven Moldin, in "Genetic science and depression: Implications for research and treatment," delineated the growth in knowledge from the Human Genome Project, the interactions of different genomes with their environments and protein products, *proteomics,* and then suggested that "the greatest benefit from genetic research is likely to come in the development of platforms for drug discovery and for understanding the genetic contributions to drug action"

			Other papers gave overviews of various treatments; in the United States, there are 20 FDA-approved antidepressants, which in general are "moderately effective," although none of them cures depression, and "a significant number of people either do not respond or respond only partially"; there are two new physical therapies—transcranial magnetic stimulation and vagus nerve stimulation—that remain to be evaluated; there is evidence that cognitive or behavioral therapy each is effective in the treatment of clinical depression; in an epilogue, Weissman observed, "treatment for depression is more targeted, faster, and with fewer side effects and is aimed at the underlying pathophysiology of depression"
Neuroimaging	United States	Andreasen NC. Mapping the mind. In: *Brave New Brain: Conquering Mental Illness in the Era of the Genome*. Oxford University Press; 2001:130; Morihisa JM, ed. Advances in Brain Imaging. American Psychiatric Association, 2001	Beginning in the 1970s and 1980s, techniques of CT and MRI showed how the brain was physically diminished in the dementias and other organic illnesses and how, in some cases of schizophrenia, the ventricles were enlarged; after this discovery, what were known as "functional techniques of neuroimaging"—including functional MRI, single photon emission computed tomography, and PET—were applied to studying changes in brain activity (blood flow) in mental illness; although Andreasen stated that most of these techniques are still research tools, she also observed that in some illnesses "PET permits us to study the relationship between drug dose and clinical response based on a measurement of the levels and activity in the brain"
The effects of traumatic events on individuals	United States, England, France, Germany, and Italy	Micale MS, Lerner P, eds. *Traumatic Pasts, Psychiatry, and Trauma in the Modern Age, 1870–1930*. Cambridge University Press; 2001	A collection of essays by scholars from different disciplines, describing how individuals in several countries suffered medical and psychological disturbances from the effects of railroad accidents, accidents at work, remembering traumatic events in their lives, and the aftermath of shell shock in World War I; in their essay "Trauma, psychiatry, and history," Lerner and Micale commented that there is no "single, uniform, transhistorically valid concept of psychological trauma," and that although it is "impossible to write a single, unilinear history of trauma," it is possible to write case histories of how individuals experienced trauma and to collate these experiences with the ideas about the nature of trauma that were held by scientists and social groups and that were dominant in the cultures in particular moments in the past
Diagnosis and treatment of borderline personality disorder	United States	Gunderson JG. *Borderline Personality Disorder: A Clinical Guide*. American Psychiatric Association; 2001; American Psychiatric Association. *Practice Guideline for the Treatment of Patients with Borderline Personality Disorder*. American Psychiatric Association; 2001; Oldham JM. A 44-year-old woman with borderline personality disorder. *JAMA*. 2002;287:1031	Gunderson' *Guide* and the APA's *Practice Guideline* recommend combinations of long-term psychotherapy (often consisting of cognitive therapy or psychodynamic psychotherapy) and medications that are targeted for specific symptoms, and include low-dose antipsychotics and SSRIs; Oldham observed that, after this treatment, "over time, most patients with borderline personality disorder show substantial improvement"
September 11, 2001, terrorist attacks on the World Trade Center and the Pentagon	United States	Kleinfield NR, Connelly M: 9/11 still strains New York psyche. Poll finds widespread unease and lingering fear of terror. *The New York Times*, September 8, 2003, Section A, pp. A1–A2; Sheehy G: Middletown America. *One Town's Passage from Trauma to Hope*. Random House; 2003; Cancelmo JA, Tylim I, Hoffenberg J, eds. *Terrorism and the Psychoanalytic Space: International Perspectives from Ground Zero*. Pace University Press; 2003	The 9/11 terrorist attacks were notable for their amalgam of violence, loss, and death and for the great variability of the mental and physical reactions that followed from these attacks; whereas some individuals have recovered and formed what Gail Sheehy describes as a "new life," others have suffered from persisting episodes of PTSD, anxiety, depression, physical symptoms, and fears that there will be new terror attacks; 5 years after the attack two-thirds of New Yorkers said they were still "very concerned" about another attack on their city (*The New York Times*, September 7, 2006)

Overviews of psychoanalysis	United States	Erwin E, ed. *The Freud Encyclopedia: Theory, Therapy, and Culture*. Routledge; 2002; Zaretsky E. *Secrets of the Soul: A Social and Cultural History of Psychoanalysis*. Knopf; 2004	The *Encyclopedia* consists of more than 200 entries by Freud scholars, which include biographical sketches of Freud (with an entry on his family) and of individuals who contributed to the development of psychoanalysis; entries on each of Freud's famous case histories; evaluations of Freud's theories of anxiety and defense, drives, the unconscious and repression, neuroses, and narcissism; the influence of psychoanalysis on such humanistic disciplines as anthropology and cultural studies, history and biography, literary criticism, film studies, and philosophy, as well as on biology and neurobiology; and the history and current state of psychoanalysis in various countries in Europe, the Americas, and Africa, as well as in Great Britain, Australia, Japan, Korea, China, India, and the Philippines *Secrets of the Soul* gives kaleidoscopic overviews of how Freud's ideas were influenced by the social, political, and cultural climates in which these ideas originated; Zaretsky argues that "the idea of a *personal* unconscious was new" and "gave expression to possibilities of individuality, authenticity, and freedom that had only recently emerged" and that then played an important role in "the modernism of the 1920s, the English and American welfare states of the 1940s and 1950s, the radical upheavals of the 1960s, and the feminist and gay-liberation movements of the 1970s"; at the same time, in ways that were complex and paradoxical, psychoanalysis became "a fount of antipolitical, antifeminist, and homophobic prejudice" and led to the creation of other psychotherapies and movements that in many cases replaced it; Zaretsky's book is a pioneering attempt to delineate the historical impact of psychoanalysis
Psychosomatic medicine	United States	Blumenfield M, Strain J, eds. *Psychosomatic Medicine*. Lippincott Williams & Wilkins; 2006	In 2003, the American Board of Psychiatry and Neurology granted a psychiatric subspecialty status to psychosomatic medicine, and in 2005, the first board examination in psychosomatic medicine was held; the book edited by Blumenfield and Strain consists of a collection of articles giving comprehensive accounts of psychosomatic symptoms in medical, psychiatric, and neurologic illnesses and how these symptoms can be treated
Confinement of the mentally ill in asylums	South Africa, Switzerland, France, Canada, Australia, Germany, United States, Japan, Argentina, Mexico, India, Nigeria, Ireland, and England	Porter R, Wright D, eds. *The Confinement of the Insane. International Perspectives, 1800–1965*. Cambridge University Press; 2003	This volume brings together 14 original research papers by different scholars, each of whom examines the social forces that influenced the confinement of the insane in asylums in different countries during different periods of time in the 19th and 20th centuries; summing up the contents of the papers, Porter concluded that the history of the growth of asylums "proves more complex than it might seem," revealing that "the asylum was neither just a site for care and cure, nor just a convenient place for locking up inconvenient people ('custodialism'). It was many things all at once. And far from being a weapon securely under the control of the [psychiatric] profession, or the state, it was a contested site, subject to continual negotiations among different parties, including families and the patients themselves"

Treatment of schizophrenia	United States	American Psychiatric Association: *Practice Guideline for the Treatment of Patients with Schizophrenia*. 2nd ed. American Psychiatric Association; 2004	Recommendations that are intended to help psychiatrists in assessing and treating adult patients with schizophrenia in their acute phase, treatment stabilization phase, and stable phase; each recommendation receives one of three categories of endorsement: Recommended with substantial confidence, recommended with moderate confidence, and may be recommended on the basis of individual circumstances; although the *Practice Guideline* is based on synthesis of "current scientific knowledge and rational clinical practice," it is emphasized that it is only a guideline, that it should not be construed to serve as a standard of medical care, and that "the ultimate judgment regarding a particular clinical procedure or treatment plan must be made by the psychiatrist in light of the clinical data presented by the patient and the diagnosis and treatment options available"
College Mental Health	United States	Kadison R, Geronimo I. *College of the Overwhelmed: The Campus Mental Health Crisis and What to Do about It*. Jossey-Bass; 2004	Delineates the mental pressures faced by college students as they confront academic requirements, explore sexuality, and form new interpersonal relationships; as a result of these pressures, "since 1988, the likelihood of a college student suffering depression has doubled, suicidal ideation has tripled and sexual assaults have quadrupled"; on the second half of the book, in a chapter entitled "For students only," Kadison and Geronimo offer proactive ways for students to maintain mental balance and how to seek help if things go wrong
A suppressed psychiatric scandal	United States	Scull A. *Madhouse: A Tragic Tale of Megalomania, and Modern Medicine*. Yale University Press; 2005	The madhouse Scull writes about was the Trenton State Hospital in New Jersey from 1907 to 1930, when Henry Cotton was its Superintendent; believing that infections of various body parts were a cause of psychiatric illness, Cotton treated psychiatric patients by surgical extirpation of these parts, which were mainly teeth and tonsils, but which also included stomachs, gallbladders, colons, testicles, and ovaries; when Adolf Meyer had the young psychiatrist Dr. Phyllis Greenacre investigate Cotton's treatments, Greenacre reported that these treatments resulted in deaths, disabilities, and questionable improvement of psychiatric symptoms; however, Meyer suppressed her report; Cotton was demoted from Superintendent to Director of Research; a public scandal was thus averted, and knowledge of Cotton's operations remained unknown for many years until Scull, after doing research based on documents and the recollections of several individuals, uncovered what had been unknown and published his book
Use of amphetamines as antidepressant drugs	United States	Rasmussen N. Making the first antidepressant: Amphetamine in American medicine, 1929–1950. *J Hist Med Allied Sci*. 2006;61:288	Shows how during the 1940s and 1950s amphetamine was a very commonly prescribed remedy for depression and related neurotic conditions, used by both general practitioners and psychiatrists; in the 1960s, although amphetamine was used in a variety of conditions, it largely stopped being used in most psychiatric cases, being replaced by the minor tranquilizers and the MAOI and tricyclic antidepressants
Recollections of treating schizophrenia	United Sates	Seeman M. Forty-five years of schizophrenia: Personal reflections. *Hist Psychiatry*. 2006;17:363	Seeman recollected that, in the 45 years since she has been treating schizophrenia, "although there have been many advances over this period, understanding of schizophrenia continues to be elusive, and treatments remain imperfect. Therefore, as perspectives shift and the ground moves beneath us, the psychiatric profession need to anchor itself firmly in the stories our [schizophrenic] patients tell us." Whether these stories "be of symptoms, of loss or of survival."

Mental health policy	United States	Frank R, Glide S. *Better But Not Well: Mental Health Policy in the United States Since 1950*. Johns Hopkins University Press; 2006	The mentally ill have improved due to the development of better-tolerated medications (selective serotonin reuptake inhibitors compared with tricyclic antidepressants) and the development of policies such as Medicare, Medicaid, Social Security Disability Insurance, and the expansion of private health insurance; however, the majority of the mentally ill are impoverished, and there has been no increase in their rates of employment; in addition, during the last 50 years their rates of homelessness have more than doubled, and incarcerations have gone up fivefold
George Mora (1923–2006), and his work in the history of psychiatry	Italy and after 1953 the United States	Works on the history of Italian psychiatry, a wide range of medical and psychiatric topics, a translation of Johann Weyer's *De praestigiis daemonum* (1991), and with Jeanne Brand, *Psychiatry and Its History: Methodological Problems in Research* (1970)	For a generation Mora was the foremost American authority on the history of psychiatry, as well as the author of the sections of the history of psychiatry for the first four editions of the *Comprehensive Textbook of Psychiatry*
Mood disorders	United States	In 2006–2007 two textbooks on mood disorders were published: Stein D, Kupfer D, Schatzberg A, eds. *The American Psychiatric Publishing Textbook of Mood Disorders*. American Psychiatric Publishing; 2006; Goodwin FK, Jamison KR. *Manic-Depressive Illness: Bipolar Disorders and Recurrent Depression*. 2nd ed. Oxford University Press; 2007 (1st ed., 1990)	Each of these books gave detailed information on the latest knowledge of the causes, symptoms, and treatments of mood disorders
Albert Ellis (1913–2007)	United States	Ellis published 75 books, including *Overcoming Procrastination, How to Live With a Neurotic, Sex Without Guilt,* and *A Guide to Rational Living*	By late 1953, Ellis had begun developing Rational Emotive Behavior Therapy (REBT), a mode of therapy that aimed at helping individuals make psychological changes by teaching them to challenge their self-defeating thoughts; in 1960, he founded the Albert Ellis Institute to promulgate his work; he continued the shift of psychotherapy from psychoanalysts and from physicians to clinical psychologists and psychiatric social workers, which had been begun by Carl Rogers; in 2003, the American Psychological Association named him the second most influential psychologist of the 20th century, second only to Rogers
Diversity, Equity, Inclusion, and Justice	United States	American Psychiatric Association issues their official position supporting the care and rights of transgender and gender nonconforming individuals.	
Mental Health Policy	United States	Mental Health Parity and Addiction Equity Act of 2008. "Fact Sheet": The Mental Health Parity and Addiction Equity Act of 2008 (MHPAEA). Accessed November 19, 2015. Available at http://www.dol.gov/ebsa/newsroom/fsmhpaea.htm	Enacted in 2008 as part of the Affordable Care Act to address loopholes created by the initial Mental Health Parity Act of 1996. The act (1) includes mental health and substance use disorder benefits in the *Essential Health Benefits;* (2) applies federal parity protections to mental health and substance use disorder benefits in the individual and small group markets; and (3) provides more Americans with access to quality health care that includes coverage for mental health and substance use disorder services.
Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United States	Saul Levin named CEO of the APA in 2013.	This makes Dr. Levin the first openly gay person to lead a national medical specialty society in the United States.

Classification of Mental Disorders	United States	American Psychiatric Association. *Diagnostic and Statistical Manual of Mental Disorders.* 5th ed. American Psychiatric Association; 2013	In 2013, this revision to the DSM-IV was published, with several important changes: Aspergers and Autism disorders were subsumed under the term *autism spectrum disorders;* criteria were added to ADHD to facilitate application across the lifespan; symptoms must now be present before age 12 (vs. age 7 in DSM-IV); subtype specifiers of schizophrenia were eliminated due to their limited diagnostic stability, low reliability, and poor validity. In bipolar disorder, a "with mixed features" specifier has been added; Addition of disruptive mood dysregulation disorder and premenstrual dysphoric disorder; bereavement exclusion now omitted from criterion of MDD; OCD and related disorders are a new diagnostic category and include hoarding disorder excoriation (skin-picking) disorder; adjustments made to criterion for trauma and stress-related disorders; creation of gender dysphoria as a new diagnostic class. Substance disorders expanded to include gambling disorder.
Mentally ill and gun violence	United States	Metzl, Johnathan M., and Kenneth T. Machleish. "Mental Illness, Mass Shootings, and the Politics of American Firearms." *Am J Public Health.* 2015: 240–249	There is increasing focus on mental illness and gun violence in the wake of several mass shootings, which reflects decades-long history of more general debates in psychiatry about guns, violence, and mental competence. Social and political rhetoric following these violent events strengthen implications that mental illness caused these events or earlier detection of these problems might have prevented them. Many states reactively enacted legislation requiring mental health clinicians to report "dangerous patients" to local officials as a way to prevent these people from obtaining firearms. Many argue that the focus should be on prevention efforts that will have a boarder impact on communities such as reexamination of gun laws and improving mental health resources.
Changes in marijuana legislation	United States (23 states)	Wilkinson, Sauel T, Stephanie Yarnell, Rajiv Radhakrishnan, Samuel A. Ball, and Deepak Cyril D'souza. "Marijuana Legalization: Impact on Pyschicians and Public Health." *Ann Rev Med.* 2014	Between 1996 and 2015, 23 states passed laws legalizing marijuana use for medical purposes after numerous studies revealed its therapeutic potential for multiple medical conditions including epilepsy, cachexia, and chronic pain. Several states have legalized small amount of marijuana for recreational use reflecting a growing shift in public opinion regarding the safety or marijuana. Marijuana use and sale remains illegal under federal law and it is still listed as schedule I substance. Many states are calling for federal decriminalization of marijuana but the debate rages on given remaining concerns about legalization and public health effects. Despite efforts to reschedule marijuana, it continues to be classified as a schedule I substance.
United States Drug Enforcement Agency	United States	Wing N. (2015, March 18). DEA Approves Study of Psychedelic Drug MDMA In Treatment of Seriously Ill Patients. Retrieved November 17, 2015, from http://www.huffingtonpost.com/2015/03/18/deadmda-study_n_6888972.htm	MDMA was classified as a schedule I substance in 1985. In the years since, recent studies have shown that the drug can be effective for mental disorders. DEA approved study of MDMA in the treatment of anxiety in people with life-threatening illness. This comes after studies showing that MDMA can be helpful for disorders like PTSD in a supervised treatment setting.
Physician-assisted suicide	United States	Dyer, Owen, Caroline White, and Aser Garcia Rada. "Assisted Dying: Law and Practice around the World." Bmj (2015): Payne, Kate. "Consider Assisted Suicide." Tennessee Nurse 78.3 (2015): n. pag. Web 17 November 2015 Kopelman, Loretta M. Physician- assisted Suicide: What Are the Issues? Kluwer Academic Publishers, 2001	Medical professional codes have long prohibited physicians involvement in assisting a patient's suicide. However, despite ethical and legal prohibitions, calls for the liberalization of this ban have grown in recent years. Oregon's law permitting physician-assisted dying passed in 1997 is the oldest in the world. Mentally competent and physically able adults who have 6 months or less to live can get prescription for sedative medications they can take to end their lives. As of 2015, several states have enacted similar legislation, but it still remains illegal in the majority of the country.

The Human Connectome Project	United States	Hagmann P, Kurant M, Gigandet X, Thiran P, Wedeen VJ, Meuli R, Thiran, JP. Mapping human whole-brain structural networks with diffusion MRI. *PLoS ONE*. 2;e597:2007. Sporns O, Tononi G, Kotter R. The human connectome: A structural description of the human brain. *PLoS Comput Biol*. 1;e42:2005.	The Human Connectome Project aims to map all of the connections in the human brain in an effort to understand how cognitive processes emerge from their morphologic substrates. The project was launched in 2009 as part of broader efforts to increase neuroscience research. The human brain is highly complex and researchers face numerous challenges in data collection, mapping neuronal pathways, and correlating functional connectivity with anatomic connectivity. Data generated from the project could offer significant contributions to research in complex neurologic and psychological disorders.
Diversity, Equity, Inclusion, and Justice	United States	The APA issues its "Apology to Black, Indigenous and People of Color for Its Support of Structural Racism in Psychiatry."	
Classification of Mental Disorders	United States	The American Psychiatric Association publishes a text revision of DSM-5 (DSM-5-TR) in 2022	

ADHD, attention-deficit/hyperactivity disorder; AIDS, acquired immune deficiency syndrome; APA, American Psychiatric Association; CNS, central nervous system; CRF, corticotropin-releasing factor; CT, computed tomography; DSM, *Diagnostic and Statistical Manual of Mental Disorders;* ECT, electroconvulsive therapy; FDA, U.S. Food and Drug Administration; HIV, human immunodeficiency virus; MAOI, monoamine oxidase inhibitor; MMPI, Minnesota Multiphasic Personality Inventory; MRI, magnetic resonance imaging; NAMI, National Alliance for the Mentally Ill; NARSAD, National Alliance for Research on Schizophrenia and Depression; NIMH, National Institute for Mental Health; NMHA, National Mental Health Association; OCD, obsessive-compulsive disorder; PET, positron emission tomography; PTSD, posttraumatic stress disorder; SSRI, selective serotonin reuptake inhibitor; TR, text revision.

This table was conceived and developed by Ralph Colp Jr, M.D., who contributed to many editions of this book and who died in 2008. It was updated by several of the editors B. Sadock with the assistance of Kristel Carrington, and then by Robert Boland.

Appendix B

Glossary of Psychiatry and Psychology Terms

A

AA Alcoholics Anonymous.

AACAP American Academy of Child and Adolescent Psychiatry.

AACDP American Association of Chairmen of Departments of Psychiatry.

AADPRT American Association of Directors of Psychiatric Residency Training, Inc.

AAMC Association of American Medical Colleges.

AAP Association of Academic Psychiatry.

ability Capacity or competence to perform an act without previous training. *Compare* aptitude.

ablation Excision of part of the body, as in lobotomy or topectomy.

ablutomania Excessive interest in bathing and cleaning oneself; commonly observed in obsessive-compulsive disorder.

abnormal Term subject to considerable variability in definition and usage, roughly the equivalent of "psychopathologic," and defined according to several criteria: **1.** *Normative* or *statistical approach,* considers as abnormal any mental or behavioral activities that deviate from culturally determined averages or norms. **2.** *Subjective approach,* regards as abnormal or psychopathologic those phenomena that cause pain or suffering or induce a person to seek help. **3.** *Theoretical approach,* considers as abnormal any deviations from a theoretical concept of normal functioning that are indicative of psychiatric illness.

abortion Spontaneous or induced expulsion of an embryo or fetus before it has reached the stage of viability, that is, before about 20 weeks of gestation.

ABPN American Board of Psychiatry and Neurology.

abreaction A process by which repressed material, particularly a painful experience or a conflict, is brought back to consciousness; in this process, the person not only recalls but relives the repressed material, which is accompanied by the appropriate affective response. *See also* catharsis.

absence seizure PETIT MAL EPILEPSY.

absolute threshold Minimum amount of stimulus needed to produce a response.

abstinence The act of refraining voluntarily from some activity, or from the use of certain substances, such as food or drugs; in psychoanalysis, refers to refraining from sexual intercourse.

abstinence syndrome WITHDRAWAL SYNDROME; DISCONTINUATION SYNDROME.

abstract attitude ABSTRACT THINKING.

abstraction The process whereby thoughts or ideas are generalized and dissociated from particular concrete instances or material objects; concreteness in proverb interpretation suggests an impairment of abstraction, as in schizophrenia.

abstract thinking Thinking characterized by the ability to assume a mental set voluntarily, to shift voluntarily from one aspect of a situation to another, to keep in mind simultaneously various aspects of a situation, to grasp the essentials of a whole and to break a whole into its parts, to discern common properties, to plan, to assume make-believe attitudes, and to think or act symbolically. The capacity for abstract thinking is frequently impaired in patients with organic mental disorders and schizophrenia. Also called abstract attitude; categorical attitude. *Compare* concrete thinking.

abulia Inability to make decisions; lack of will.

abuse **1.** To attack or injure physically or psychologically, most commonly children, the older adults, and marital partners. *See also* battered child syndrome. **2.** To misuse substances such as drugs, illegal or prescribed, or alcohol so as to impair functioning.

acalculia Loss of ability to do calculations; not caused by anxiety or impairment in concentration. Occurs with neurologic deficit and learning disorder.

acarophobia Abnormal fear of minute animate (insects, worms) or inanimate (pins, needles) objects.

acatalepsia Severe mental deficiency characterized by the inability to reason or comprehend.

acataphasia Disordered speech in which statements are incorrectly formulated. Patients may express themselves with words that sound like the ones intended but that are not appropriate to the thoughts, or they may use totally inappropriate expressions.

acathexis Lack of feeling associated with an ordinarily emotion-charged subject; in psychoanalysis, denotes the patient's detaching or transferring of emotion from thoughts and ideas. Occurs in anxiety, dissociative, schizophrenic, and bipolar disorders. Also called decathexis. *Compare* cathexis.

accelerated interaction A term used in group therapy to refer to an extended group therapy session that may last for hours, sometimes a day. Alternate term for marathon group session.

accident proneness Tendency to have accidents as a result of psychological causes.

accreditation A voluntary process by which standards for hospitals and health facilities are approved by city or federal government agencies; may also refer to being credentialed by the American Board of Psychiatry and Neurology (ABPN). *See also* board-certified psychiatrist.

acenesthesia Loss of sensation of physical existence.

acetylcholine A neurotransmitter that causes cardiac inhibition, vasodilation, gastrointestinal peristalsis, and other parasympathetic effects; plays a critical role in memory, sleep, and the regulation of mood.

achluophobia Abnormal fear of the dark.

acid Slang for lysergic acid diethylamide (LSD).

ACLP Academy of Consultation-Liaison Psychiatry

ACP American College of Physicians.

acquired immunodeficiency syndrome (AIDS) According to the U.S. Centers for Disease Control, "a disease, at least moderately predictive of a defect in cell-mediated immunity, occurring in a person with no known cause for diminished resistance to that disease. Such diseases include Kaposi sarcoma (KS), *Pneumocystis carinii* pneumonia (PCP), and other serious opportunistic infections." The disease is caused by the human immunodeficiency virus type 1 (HIV-1). *See also* AIDS dementia complex.

acromegaly Disorder marked by hypersecretion of growth hormone by the anterior pituitary resulting in characteristic enlargement of certain body structures, such as the head, hands, feet, lips, and jaw; often associated with somnolence, moodiness, and decreased libido.

acrophobia Abnormal fear of high places.

acting out Behavioral response to an unconscious drive or impulse that brings about temporary partial relief of inner tension; relief is attained by reacting to a present situation as if it were the situation that originally gave rise to the drive or impulse. Common in borderline states.

activity group psychotherapy Type of group therapy, introduced and developed by S. R. Slavson, designed for children and young adolescents, emphasizing emotional and active interaction in a permissive, nonthreatening atmosphere; the therapist interprets behavior and stresses reality testing.

actualization

Realization of one's full potential. *See also* individuation.

aculalia Nonsense speech associated with marked impairment of comprehension. Occurs in mania, schizophrenia, and neurologic deficit.

acute stress disorder Severe emotional reaction resulting from extreme environmental stress such as the death of a loved one, a disaster, or a catastrophic life situation. It usually remits within hours or days; however, if it persists for over a month it may evolved into a condition called posttraumatic stress disorder (PTSD).

ADAMHA Alcohol, Drug Abuse, and Mental Health Administration.

adaptation Process of fitting or conforming to the environment by behavioral or psychic changes that promote optimal functioning. *See also* adjustment.

adaptational approach In analytic therapy, consonant with Sandor Rado's formulations on adaptational psychodynamics, therapy focusing on the maladaptive patterns used by patients in the treatment sessions, on how those patterns developed, and on what the patients must do to overcome them and stabilize their functioning at self-reliant, adult levels. *See also* social adaptation.

adaptive behavior Any behavior that increases an organism's ability to adjust to a specific environment or situation.

ADD Attention-deficit disorder, usually referred to as Attention Deficit/Hyperactivity Disorder (ADHD).

addiction Repeated and increased use of a drug or chemical substance, the deprivation of which gives rise to symptoms of distress and an irresistible urge to use the agent again, leads to deterioration of physical and mental health. *See also* drug dependence.

ADHD Attention-deficit hyperactivity disorder.

adiadochokinesis Inability to perform rapid alternating movements. Occurs with neurologic deficit and cerebellar lesions.

adjustment Maladaptive reaction to identifiable circumstances or life events that is expected to remit when the stress ceases. In DSM-5, divided into the following subtypes based on symptoms: with anxiety, with depressed mood, with mixed anxiety and depressed mood, with disturbance of conduct, with mixed disturbance of emotions and conduct, and unspecified.

adjustment disorder Maladaptive reaction to identifiable circumstances or life events that is expected to remit when the stress ceases.

Adler, Alfred (1870–1937) Viennese psychiatrist and one of Freud's original followers who broke with him and introduced and developed the concepts of individual psychology, inferiority complex, and overcompensation. *See also* masculine protest.

adlerian Attributed to or described by Alfred Adler.

administrative psychiatry Psychiatry concerned with public affairs, policy-making, executive decisions, and the duties of persons in executive positions.

adolescence Period of growth from puberty to maturity. Its beginning is marked by the appearance of secondary sexual characteristics, usually at about age 12; termination is marked by the achievement of sexual maturity at about age 20. *See also* psychosexual development.

adolescent mania Signs of mania occurring in an adolescent as the result of substance abuse (including alcohol) or of antisocial behavior but not as the result of a true bipolar disorder.

adrenaline EPINEPHRINE.

adrenergic 1. Relating to nerve fibers, tracts, or pathways in which synaptic transmission is mediated by norepinephrine (e.g., the sympathetic division of the autonomic nervous system), more generally, to processes activated by epinephrine or norepinephrine. **2.** Relating to drugs (catecholamines) that mimic the actions of the sympathetic nervous system.

adrenergic system Nerve cells or fibers of the autonomic nervous system that employ norepinephrine as their neurotransmitter.

Advanced sleep phase circadian rhythm disorder A circadian rhythm sleep–wake disorder characterized by sleep–wake times that are earlier than conventional times; individuals with this disorder are referred to as “early birds” or “larks.”

adventitious reinforcement Responses that are reinforced accidentally by the coincidental pairing of response and reinforcement; such events may have clinical implications in the development of phobias or other neurotic behavior.

adverse effects Secondary, unfavorable reactions or results; usually referring to side effects of drugs.

adynamia Weakness and fatigability, a characteristic of neurasthenia and depression.

adynamic ileus PARALYTIC ILEUS.

aerophagia Excessive swallowing of air. Seen in anxiety disorder.

affect The subjective and immediate experience of emotion attached to ideas or mental representations of objects. Affect has outward manifestations that may be classified as restricted, blunted, flattened, broad, labile, appropriate, or inappropriate. *See also* mood.

affect-fantasy Jung's term for an emotional-laden fantasy.

affectionate transference *See* transference.

affective disorder *See* MOOD DISORDER.

affective hallucination Hallucination in which the content is either grandiose or self-deprecatory or involves other features common to a depressive syndrome such as guilt, disease, or poverty.

affective interaction Interpersonal experiences and exchanges that are emotionally charged.

aftercare After hospitalization, a continuing program of rehabilitation designed to reinforce the effects of therapy and to help patients adjust to their environment.

ageism Prejudice or discrimination against a particular age group, especially the older adults.

ageusia Lack or impairment of the sense of taste; may be seen in depression and neurologic deficit.

aggression Forceful behavior, verbal or physical, usually directed against another person.

aggressive drive One of the two primal drives or instincts (the other is the sexual drive) in Freud's dual-instinct psychoanalytic theory. It is conceived of as an unconscious destructive drive or an impulse directed at oneself or another that aims toward dissolution and death and operates on the repetition–compulsion principle, in contrast to the sexual drive, which follows the pleasure–pain principle. Also called death instinct, Thanatos.

aging The process of growing old; in human physiology, aging is said to occur when there is a failure to replace cells in sufficient numbers to maintain full functional capacity.

agitated depression Major depressive disorder with psychomotor agitation as a primary sign and symptom, characterized by restlessness, increased motor activity, and racing thoughts.

agitation State of anxiety associated with severe motor restlessness.

agnosia Inability to understand the import or significance of sensory stimuli; cannot be explained by a defect in sensory pathways or sensorium. In strict usage, diagnosis of agnosia implies an organic cerebral lesion; however, the term has also been used to refer to the selective loss or disuse of knowledge of specific objects due to emotional circumstances, as seen in certain schizophrenic, hysteric, and depressed patients. For types of agnosia, see the specific term.

agonist In pharmacology, a substance that excites the receptor sites of the cell and promotes or enhances a biologic response. *Compare* antagonist.

agoraphobia Morbid fear of open places or of leaving the familiar setting of the home; may be present with or without panic attacks.

agraphia Loss or impairment of a previously possessed ability to write.

aichmophobia Abnormal fear of pointed objects.

AIDS Acquired immunodeficiency syndrome.

AIDS dementia complex Neurologic complication of AIDS characterized by confusion, impaired judgment, impulsive behavior, and psychosis. Also called AIDS encephalopathy.

ailurophobia Abnormal fear of cats.

akathisia State of motor restlessness manifested by a compelling need to be in constant movement; may be seen as an extrapyramidal side effect of phenothiazine or other antipsychotic medication.

akinesia Lack of physical movement, as in the extreme immobility of catatonic schizophrenia; may also occur as an extrapyramidal effect of antipsychotic medication.

akinetic mutism Absence of voluntary motor movement or speech in a patient who is apparently alert (as evidenced by following eye movements). Seen in psychotic depression and catatonic states.

Al-Anon Organization of relatives of alcoholics, patterned after Alcoholics Anonymous, which promotes the discussion and resolution of common problems.

Alateen Organization directed to children of alcoholics, through group support, so that they may better understand their parents' alcoholism. *See also* Alcoholics Anonymous.

alcohol abuse and dependence Called alcohol use disorder in DSM-5. *See also* alcoholism.

alcohol amnestic disorder Alternative term for Korsakoff psychosis.

alcohol dementia WERNICKE SYNDROME.

alcoholic blackout Amnesia experienced by alcoholics concerning behavior during drinking bouts; usually indicates that reversible brain damage has occurred.

alcoholic deterioration Dementia and mental deterioration associated with chronic excessive alcohol use. Called dementia associated with alcoholism in DSM.

alcoholic hallucinosis Occurrence of hallucinations with a clear sensorium in a person with a history of heavy drinking and alcohol dependence; usually follows a prolonged drinking bout. *See also* Delirium tremens.

alcoholic psychosis Mental disorder that results from alcoholism and that involves organic brain damage, as in delirium tremens and Korsakoff psychosis.

Alcoholics Anonymous (AA) An organization of alcoholics formed in 1935 that uses certain group methods, such as inspirational-supportive techniques, to help rehabilitate chronic alcoholics.

alcohol idiosyncratic intoxication Syndrome of marked alcohol intoxication with subsequent amnesia for the period of intoxication produced by the ingestion of quantities of alcohol that would be insufficient to induce intoxication in most people. Also called pathologic intoxication.

alcohol intoxication Constellation of specific neurologic, psychological, and behavioral effects produced by the recent ingestion of alcohol; characteristically, the effects include slurred speech, motor ataxia, disinhibition of sexual or aggressive impulses, lability of mood, impairment of attention or memory, and impairment of judgment. *See also* intoxication.

alcoholism Excessive dependence or addiction to alcohol, usually to the point that the person's physical and mental health are threatened or harmed; may be episodic or continuous. Called alcohol use disorder in DSM-5.

alcohol withdrawal syndrome Symptom complex resulting from the cessation or reduction in alcohol intake in a person who has been drinking heavily; includes tremulousness, seizures (rum fits), hallucinations, and autonomic hyperactivity (delirium tremens). *See also* withdrawal syndrome.

Alexander, Franz (1891–1964) Hungarian psychoanalyst who founded the Chicago Institute for Psychoanalysis, developed the concept of corrective emotional experience and specificity hypothesis in psychosomatic disorders, and, in collaboration with Thomas French in 1946, identified most of the basic characteristics of brief dynamic psychotherapy.

alexia Loss of the power to understand the meaning of written or printed words and sentences. *Compare* dyslexia.

alexithymia Inability or difficulty in describing or being aware of one's emotions or moods; associated with depression, substance abuse, and posttraumatic stress disorder.

algophobia Abnormal fear of pain.

algorithm Graphic representation used as a set of instructions for solving diagnostic or clinical problems. Also called decision tree.

alienation In psychiatry, used to describe a person's feelings of detachment from self or society, to denote one's avoidance of emotional experiences, or to describe efforts to estrange oneself from one's own feelings. *Compare* relatedness. *See also* isolation.

alienist Obsolete term for a psychiatrist who offers expert opinion about a person's mental health or sanity.

allergic jaundice Relatively rare, unpredictable, non–dose-dependent hypersensitivity reaction after treatment with some phenothiazines; generally appears during the second to fourth weeks of therapy, resulting in hyperbilirubinemia and deposition of bile pigment in the skin and mucous membranes which causes a yellow appearance of the patient; an obstructive (cholestatic) type of jaundice manifested by predominantly conjugated (direct-reacting) hyperbilirubinemia, the presence of bilirubin in the urine, and an abnormally high plasma alkaline phosphatase.

alliance *See* therapeutic alliance.

allied health professional *See* paraprofessional.

alloplasty Adaptation to stress by attempting to change the environment. *Compare* autoplasty.

Allport's group relations theory Theory developed by Gordon W. Allport that a person's behavior is influenced by their personality and the need to conform to social forces; illustrates the interrelationship between group therapy and social psychology.

alogia Inability to speak because of mental deficiency or an episode of dementia.

alopecia Hair loss. *See* trichotillomania.

alpha (α) error TYPE 1 ERROR.

alpha waves As measured by an electroencephalogram (EEG), brain waves that are 8 to 13 Hz, indicating a relaxed, waking state.

ALS Amyotrophic lateral sclerosis.

alternating role Pattern characterized by periodic switching from one type of behavior to another.

altruism Regard for and dedication to the welfare of others; a term originated by the French philosopher Auguste Comte (1798–1857). In psychiatry, the term is closely linked with ethics and morals; Freud recognized altruism as the only basis for the development of community interest; Bleuler equated it with morality.

Alzheimer disease DEMENTIA OF THE ALZHEIMER TYPE.

AMA American Medical Association.

ambivalence Presence of strong and often overwhelming simultaneous contrasting attitudes, ideas, feelings, and drives toward an object, person, or goal; term coined by Bleuler, who differentiated three types: affective ambivalence, intellectual ambivalence, and ambivalence of the will. Commonly seen in schizophrenia and borderline personality disorder.

ambulatory schizophrenia A descriptive term refers to schizophrenic mental illness that is sufficiently well compensated so as not to require continuous hospitalization.

amentia Lack of intellectual development as a result of inadequate brain tissue. *Compare* dementia.

American Academy of Child and Adolescent Psychiatry (AACAP) Organization of child and adolescent psychiatrists, founded in 1953, whose objectives are to study and advance medical contributions to the knowledge and treatment of psychiatric illnesses of children and adolescents.

American Association of Chairmen of Departments of Psychiatry (AACDP) Organization of chairpersons of departments of psychiatry, founded in 1967, that concentrates on promoting medical education, research, and patient care, especially as they relate to psychiatry; prompting the growth and development of psychiatry; and providing a forum for discussion among chairpersons.

American Association of Directors of Psychiatric Residency Training, Inc. (AADPRT) Organization of training directors of U.S. psychiatric residency programs, founded in 1973, whose mandate is to oversee standards of approved residency criteria and to further psychiatric education.

American Board of Psychiatry and Neurology (ABPN) Group, founded in 1934 that sets the standards for teaching and training in psychiatry and neurology in American hospitals and training centers. Its members are from the American Medical Association, American Psychiatric Association, and American Neurological Association and is a member of the American Board of Medical Specialties. It conducts periodic examinations of those who have satisfactorily completed their training; upon passing the examination, candidates are certified to practice the specialty of psychiatry and/or neurology and/or child psychiatry. It also oversees continued certification for psychiatrists and neurologists.

American College of Physicians (ACP) Honorary organization of internists and related medical specialists, founded in 1915, that sponsors postgraduate courses for physicians as well as teaching and research scholarships.

American College of Psychiatrists (ACP) Honorary organization of senior psychiatrists, founded in 1963, established to honor persons who have made a significant contribution to the study and development of psychiatry in the United States.

American Law Institute formulation of insanity Legal definition of insanity whereby a person is absolved of criminal responsibility if, as a result of a mental disorder, he “lacks substantial capacity either to appreciate the wrongfulness of his conduct or to conform his conduct to the requirements of law.” *See also* Durham rule; M’Naghten rule.

American Medical Association (AMA) National organization of medical doctors of all specialties, founded in 1847, whose mandate is to monitor the educational, training, and research concerns of the medical profession; plays an advisory role in national legislation related to health care and disseminates medical information.

American Neurological Association (ANA) National organization of neurologists, founded in 1875 that conducts research and educational programs; also elects members to the American Board of Psychiatry.

American Psychiatric Association (APA) Most important and largest professional organization of American physicians who specialize in the practice of psychiatry. The organization was founded in 1844 by 13 superintendents (“original thirteen”) as the Association of Medical Superintendents of American Institutions for the Insane; in 1891, the name was changed to the American Medico-Psychological Association and in 1921 to its present name. Its purpose is to advance the development of psychiatric education, research, and practice in the United States.

American Psychoanalytic Association (APA) National organization of graduates of various psychoanalytic training programs, founded in 1911, mandated to establish and maintain standards for the field of psychoanalysis and the training of psychoanalysts and to encourage research; historically represents orthodox schools of classical psychoanalysis derived from Freudian theory.

American Psychological Association Founded in 1892, largest and most important organization of American psychologists who specialize in experimental, clinical, research, and educational psychology, and many other subspecialties in psychology; sometimes known as the “big APA” to distinguish it from the smaller American Psychiatric Association.

amimia Lack of ability to make gestures or to comprehend those made by others.

amines Organic compounds derived from ammonia by replacing hydrogen atoms with organic groups, such as the catecholamines.

amino acid Organic acid in which one of the CH hydrogen atoms has been replaced by NH_2; structured building blocks of proteins that function as neurotransmitters similar to the biogenic amines, probably in 60% to 70% of the synapses in the brain.

amnesia Disturbance in memory manifested by partial or total inability to recall past experiences. For types of amnesia, see the specific term.

amnestic aphasia, amnesic aphasia Disturbed capacity to name objects, even though they are known to the patient. Also called anomic aphasia.

amnestic disorder Mental syndrome in which impairment of memory is the predominant cognitive defect; in DSM-5, called major or minor neurocognitive disorder due to another medical condition.

amok Condition, usually associated with Malayan men, characterized by a sudden, unprovoked outburst of wild rage usually culminating in homicide.

amphetamine Central nervous system stimulant with a chemical structure and action closely related to the sympathomimetic amines; used to treat depression, attention-deficit hyperactivity disorder, hypersomnia, and narcolepsy; may be abused to prolong wakefulness and attentiveness.

amygdala Part of the basal ganglia complex in the dorsomedial portion of the temporal lobe: it and the hippocampus are major components of the limbic system and have been implicated in the production of memory, emotions, and violent behavior.

amyotrophic lateral sclerosis (ALS) Degenerative neuromuscular disease, caused by a slow virus, with an insidious onset beginning between the ages of 50 and 70; wasting begins in upper limbs, eventually spreading to the tongue, mouth, and palate. Degeneration of both pyramidal tracts above the medulla produces pseudobulbar palsy, which, when severe, results in impaired voluntary control of emotional reactions, which consequently, may be exaggerated, explosive, and quite inappropriate. Also called Lou Gehrig disease.

Amytal interview Psychiatric interview conducted with the patient having received an intravenous infusion of amobarbital (Amytal), which produces an altered state of consciousness during which repressed memories and feelings may be recalled or reexperienced; used in the treatment of dissociative states, psychogenic amnesia, and conversion disorder.

ANA American Neurological Association.

anaclitic Depending on others, especially as the infant on the mother; anaclitic depression in children results from an absence of mothering.

anaclitic therapy Psychotherapy characterized by allowing the patient to regress; used mainly in the treatment of psychosomatic disorders.

anal character Freud's term to describe persons who are perfectionistic, parsimonious, punctual, and stubborn.

analeptic PSYCHOMOTOR STIMULANT.

anal erotism Pleasurable experience felt by a child in the anal area during the anal phase of psychosexual development.

analgesia State in which one feels little or no pain.

anal phase Second stage in psychosexual development, occurring when a child is between the ages of 1 and 3 years. During that period, activities, interests, and concerns are centered on the anal zone, and the pleasurable experience felt in that area is called anal erotism. *See also* infantile sexuality; psychosexual development.

analysand In psychiatry, the one who is being analyzed.

analysis in depth PSYCHOANALYSIS.

analysis of variance (ANOVA) Statistical technique designed to compare two or more groups of observations by which sets of measurements are investigated to find out to what extent they are determined by experimental influences or chance influences. *See also* variance.

analytic psychology Jung's system of psychology, characterized by a belief in the collective unconscious or objective psyche, the archetype, and the complex.

anamnesis Medical history of a patient, particularly used in connection with the patient's own recollections.

anancasm Repetitious or stereotyped behavior or thought usually used as a tension-relieving device. Alternate spelling, anankastic.

anankastic personality OBSESSIVE-COMPULSIVE PERSONALITY.

ancillary care Auxiliary, accessory, or secondary services provided in the treatment or rehabilitation of patients.

androgen Hormone that is produced in the testes and the adrenal glands and that stimulates activity of the accessory male sex organs, promotes development of male sex characteristics, or prevents changes in the latter following castration; for example, testosterone. *Compare* estrogen.

androgyny Combination of female and male characteristics in one person. *See also* bisexuality.

androphobia Irrational fear of men.

anergia Lack of energy.

anergic schizophrenic BURNED-OUT SCHIZOPHRENIC.

anesthesia Absence of sensation. *See also* hysterical anesthesia.

angel dust Street term for phencyclidine (PCP).

anhedonia State of being unable to experience pleasure. *Compare* hedonism.

anima According to jungian psychology, the person's inner self, as opposed to the self that one presents to the outside world (persona).

Anna O A patient of Joseph Breuer and Sigmund Freud whose arm became paralyzed whenever she was unconsciously reminded of her feelings for her father (she had been sitting at his bedside with her arm pressed against the side of his bed at the time of his death). The motor disturbance represented an action that was associated with an objectionable infantile sexual impulse. Later identified as Bertha Pappenheim who became a noted feminist, social pioneer, and founder of the Jewish Women's Association.

anniversary reaction Behavior, symptoms, or dreams that occur at the same time of year as a significant past event.

anomia Inability to recall the names of objects.

anomic aphasia AMNESTIC APHASIA.

anomie Term, popularized by Émile Durkheim as a major cause for suicide, referring to a sense of alienation and despair resulting from the loss or weakening of previously valued norms, ideals, or goals.

anorectic Drug that decreases appetite.

anorexia nervosa Serious and sometimes life-endangering condition characterized by a disturbed body image and self-imposed severe dietary limitation, usually resulting in serious malnutrition; appetite usually remains intact.

anorgasmia Inability to achieve orgasm in the female. *See also* frigidity.

anosognosia Unawareness or nonacceptance of a neurologic deficit.

anosomnia Loss of ability to smell.

ANOVA Analysis of variance.

antagonist In pharmacology, a substance that reduces or blocks the action of another; for example, naloxone (Narcan) is used in the treatment of opioid overdose because it is reverses the effects of narcotics. *Compar*e agonist.

anterograde amnesia Loss of memory for events subsequent to the onset of the amnesia. *Compare* retrograde amnesia.

anthropology Study of humans in relation to distribution, origin, classification, and relationship of races, physical characteristics, environmental and social relations, and culture.

antianxiety drug ANXIOLYTIC.

anticholinergic Drug that blocks the actions of atropine; primarily used in the treatment of medication-induced movement disorders. *See also* antiparkinsonism drug.

anticholinergic effect Effect, such as a dry mouth and blurred vision, due to a blockade of the cholinergic (especially the parasympathetic) nerves; often seen as a side effect of therapy with phenothiazine and tricyclic antidepressant drugs.

anticipation Term implying careful planning or worrying, and premature but realistic expectation of dire and potentially dreadful outcomes, in goal-directed inner discomfort.

anticonvulsant Any drug with the ability to prevent the excessive discharge of neurons in the brain and thus lower the threshold for convulsions or seizures. Also called antiepileptic drug.

antidepressant drug Any of a class of psychotherapeutic drugs used in the treatment of pathologic depression. Two main categories are the cyclic antidepressants and the monoamine oxidase inhibitors; more recently, serotonergic agents such as fluoxetine. Lithium carbonate also has antidepressant activity in certain patients.

antiepileptic drug ANTICONVULSANT.

antimanic drug Drug used to alleviate the symptoms of mania; lithium is particularly effective in preventing relapses in bipolar disorder.

antiparkinsonism drug Drug that relieves the symptoms of parkinsonism and is effective in countering the extrapyramidal side effects often induced by antipsychotic drugs by acting on the central nervous system to diminish skeletal muscle tone and involuntary movements. Levodopa, the agent of choice for Parkinson disease, does not antagonize the extrapyramidal effects of antipsychotic drugs. Anticholinergic agents, such as benztropine and trihexyphenidyl, effectively counteract drug-induced parkinsonism but are now secondary drugs in the treatment of Parkinson disease.

antipsychotic Any of a class of psychotherapeutic drugs used to treat psychosis, particularly schizophrenia. Also called neuroleptic; major tranquilizer; ataractic drug.

antisocial behavior Behavior pattern of such marginal criminal types as racketeers, prostitutes, and illegal gamblers. Formerly called sociopathic behavior. In lay usage often confused with asociality. *See also* antisocial personality disorder.

antisocial personality disorder Disorder characterized by an inability to get along with other members of society and by repeated conflicts with individual persons and groups; common attributes include impulsiveness, egocentricity, hedonism, low frustration tolerance, irresponsibility, inadequate conscience development, exploitation of others, and rejection of authority and discipline. *See also* antisocial behavior.

Anton syndrome Disorder caused by a lesion in the occipital lobe of the brain that causes blindness which the patient denies experiencing.

Anxiety Unpleasurable emotional state associated with psychophysiological changes in response to an intrapsychic conflict; in contrast to fear, the danger or threat in anxiety is unreal. Psychological changes consist of an uncomfortable feeling of impending danger, an overwhelming awareness of being powerless, inability to perceive the unreality of the threat, prolonged feeling of tension, and exhaustive readiness for the expected danger; physiologic changes consist of increased heart rate, disturbed breathing, trembling, sweating, and vasomotor changes. *Compare* fear.

anxiety disorder Disorder in which anxiety is the most prominent disturbance or in which patients experience anxiety if they resist giving in to their symptoms. In DSM, anxiety disorders include separation anxiety disorder, selective mutism, panic disorder with agoraphobia, agoraphobia without history of panic disorder, social phobia, simple phobia, and generalized anxiety disorder.

anxiety disorders of childhood or adolescence Disorders characterized by chronic anxiety, unrealistic fears, hypersensitive autonomic responses, or fear of leaving home; patients are usually immature, inhibited, timid, approval-seeking, and apprehensive in new situations or places.

anxiety hysteria PHOBIC DISORDER.

anxiety neurosis As initially described by Sigmund Freud, a syndrome characterized by general irritability, anxious expectation, pangs of conscience, anxiety attacks, and phobias. Called generalized anxiety disorder in DSM.

anxiety state Disorder characterized by panic and anxious overconcern; somatic symptoms are often prominent.

anxiolytic Any of a class of psychotherapeutic drugs used to treat pathologic anxiety and its related symptoms; includes the benzodiazepines and buspirone. Also called antianxiety drugs; minor tranquilizers.

APA American Psychiatric Association; American Psychoanalytic Association; American Psychological Association.

apathetic withdrawal *See* withdrawal.

apathy Want of feeling or affect, a lack of interest and emotional involvement in one’s surroundings; observed in certain types of schizophrenia and depression.

Apgar scores Measurements taken 1 and 5 minutes after birth to determine physical normality in the neonate; scores are based on color, respiratory rate, heartbeat, reflex action, and muscle tone.

aphasia Any disturbance in the comprehension or expression of language due to a brain lesion. For types of aphasia, see the specific term.

aphonia Loss of voice.

aphrodisiac Substance or drug that increases sexual desire.

apnea Temporary cessation of breathing. *See* obstructive sleep apnea syndrome.

apoplexy Old classical term for cerebrovascular accident.

apperception Awareness of the meaning and significance of a particular sensory stimulus as modified by one's own experiences, knowledge, thoughts, and emotions. *See also* perception.

appetitive phase First stage in the sexual response cycle, as described by Masters and Johnson, characterized by sexual fantasies and the desire to have sex.

appropriate affect Emotional tone in harmony with the accompanying idea, thought, or speech.

apraxia Inability to perform a voluntary purposeful motor activity; cannot be explained by paralysis or other motor or sensory impairment. In constructive apraxia, a patient cannot draw two- or three-dimensional forms.

aptitude Potential to acquire competence or skill if trained. *Compare* ability.

archetype Jung's term for the symbols used by individuals to express the collective experience of the human race. *See also* collective unconscious.

arithmetic disorder DEVELOPMENTAL ARITHMETIC DISORDER.

arousal The establishment and maintenance of a physiologic or psychological state of being awake, alert, or responsive to stimuli. *See also* hyperarousal.

arteriosclerosis Degenerative condition marked by loss of elasticity, hardening, and thickening of the arteries, with progressive narrowing of their lumina and gradual obstruction to blood flow; organic mental disorder may develop when cerebral arteries are involved in the degenerative process.

artificial intelligence Computer production of a pattern of output that would be considered intelligent if displayed by human beings.

art therapy Treatment procedure that uses the spontaneous creative work of the patient; for example, persons make and analyze drawings, which are often expressions of their underlying emotional problems.

asociality Indifference to social values or customs, withdrawal from society, as seen in a recluse or a regressed schizophrenic person.

Asperger syndrome Term previously used to describe a condition that develops in infancy and is associated with impaired social interaction and restricted and stereotyped patterns of behavior, but without significant delays in language or cognitive development. In DSM-5, the behavioral condition of Asperger syndrome is subsumed in Level I of the autism spectrum. *See also* autism spectrum disorder.

assertiveness training Behavior therapy that involves teaching frank and direct interpersonal expression of feelings and ideas.

assessment The evaluation of a patient that leads to diagnosis and treatment.

assimilation Subjective process that involves filtering the world through one’s own system of knowledge, that is, taking in of new experience through one’s established mental structure.

association Relation between ideas or feelings. *See* clang association; loosening of associations.

Association of American Medical Colleges (AAMC) Organization of American medical schools and teaching hospitals, founded in 1876, concerned with the advancement and improvement of medical education, biomedical research, and health care in the United States.

astasia-abasia Inability to stand or walk in a normal manner, even though normal leg movements can be performed in a sitting or lying down position; seen in conversion disorder.

astereognosis Inability to identify familiar objects by touch; cannot be explained by an impairment of elementary sensory pathways or a depressed sensorium. *See also* neurologic amnesia.

asthenic personality Disorder characterized by lack of enthusiasm, fatigability, lack of capacity for enjoyment, and low tolerance for stress. *See also* adynamia; anhedonia.

astraphobia, astrapophobia Abnormal fear of thunder and lightning.

asyndesis Disorder of language, commonly seen in schizophrenia, in which the patient combines unconnected ideas and images.

ataque de nervios A syndrome, usually found in Latin American cultures, characterized by uncontrollable shouting, crying, trembling, and physical or verbal aggression.

ataractic drug ANTIPSYCHOTIC.

ataxia Lack of coordination, either physical or mental. **1.** In neurology, refers to loss of muscular coordination. **2.** In psychiatry, the term "intrapsychic ataxia" refers to lack of coordination between feelings and thoughts; seen in schizophrenia and in severe obsessive-compulsive disorder.

athetosis Movement disorder characterized by involuntary, slow, writhing, worm-like movements of the fingers and extremities; a form of extrapyramidal dyskinesia.

atonia Lack of muscle tone. *See* waxy flexibility.

attachment According to John Bowlby, the affective tie between infant and mother or primary caregiver, the disruption of which heightens vulnerability to depression or anxiety. *See also* bonding.

attachment disorder of infancy Absence or disruption of behaviors that serve to anchor the infant to its mother or primary caregiver and that produce abnormal reactions in the infant's behavior.

attachment learning Theory that learning is enhanced in the presence of the person to whom one is attached or affiliated; applies especially to infant learning.

attention Concentration; the aspect of consciousness that relates to the amount of effort exerted in focusing on certain aspects of an experience, activity, or task.

attention-deficit hyperactivity disorder (ADHD) DSM-5 diagnosis for a childhood mental disorder characterized by a developmentally inappropriate short attention span, hyperactivity, and poor concentration that cause clinically significant impairment in functioning. The category subsumes abnormal behavior patterns that had historically been referred to by a variety of names, including hyperkinetic syndrome, hyperactive child syndrome, and minimal brain dysfunction. If hyperactivity is not present, the disorder is called attention-deficit disorder (ADD).

attitude Preparatory mental posture with which one receives stimuli and reacts to them.

attributable risk Absolute incidence of a disease in exposed individuals that can be attributed to the exposure.

atypical In psychiatry, denoting an unusual or rare variant of a known disorder.

atypical child Child with distorted personality development; often used in connection with brain-damaged or autistic children.

atypical depression Diagnosis used to describe depression characterized by weight gain and hypersomnia rather than weight loss and insomnia.

atypical psychosis Disorder whose psychotic features are related to a specific culture (e.g., koro); a certain time or event (e.g., postpartum psychosis); or a unique symptomatology (e.g., Capgras syndrome). In DSM, depending on the specific syndrome, may be diagnosed as Other Specified Schizophrenia Spectrum and Other Psychotic Disorder.

audit *See* medical audit.

auditory agnosia The inability to recognize specific sounds in the context of intact hearing.

auditory amnesia NEUROLOGIC AMNESIA.

auditory hallucination Hallucination primarily involving sound.

aura 1. Warning sensations that a person usually experiences just before an epileptic seizure. **2.** Sensory prodrome that precedes a classic migraine headache.

authority figure Real or projected person in a position of power; transferentially, a projected parent.

autism *See* autistic thinking; infantile autism.

autistic spectrum disorder A range of behavioral abnormalities that begin in infancy and are characterized by deficits in social communication; failure to communicate; lack of empathy; abnormalities in eye contact; repetitive patterns of activities; stereotyped or absent speech; and either hyper- or hypoarousal to the environment. In DSM-5, autism spectrum disorder is classified into three levels based on degrees of impairment in speech and social interaction. *See also* Asperger syndrome; Rett syndrome; childhood disintegrative disorder.

autistic thinking Thinking in which the thoughts are largely narcissistic and egocentric, with emphasis on subjectivity rather than objectivity, and without regard for reality; used interchangeably with autism and dereism.

autoerotic asphyxia Asphyxia caused by intentional strangulation while masturbating in order to intensify orgasm through reduction of oxygen blood flow to the brain. High risk of death.

autoerotism 1. Sexual arousal of oneself without the participation of another person; term coined by Havelock Ellis, which is presently used interchangeably with masturbation. **2.** In psychoanalysis, a primitive phase in object relationship development preceding the narcissistic stage; in narcissism, there is a love object, but there is no love object in autoerotism.

autogynephilia A gender identity disorder in which a male becomes sexually aroused by imagining themselves transformed into a woman.

automatic judgment Reflex performance of a way of acting based on a fixed set of beliefs or values.

automatic obedience Compliance to commands without exercising critical judgment; a feature of catatonia.

automatism Undirected behavior not controlled by conscious thought.

automysophobia Abnormal fear of smelling bad or of being unclean.

autonomic nervous system Part of the nervous system that functions outside of consciousness and that directs such visceral functions as respiration, heart rate, and digestion; subdivided into sympathetic (adrenergic) and parasympathetic (cholinergic) divisions.

autonomic side effect Disturbance of autonomic nervous function that may result from the use of antipsychotic or antidepressant drugs, particularly the phenothiazine and tricyclic derivatives. Common side effects of such agents include orthostatic hypotension, blurred vision, nasal congestion, dry mouth, and constipation; such anticholinergic effects are more prominent with tricyclic antidepressants than with phenothiazines.

autonomous ego function Operation present at birth, such as perception, intuition, thinking, speaking, language, and aspects of motor development; first described by Heinz Hartmann. *See also* ego psychology.

autophobia Abnormal fear of being alone or of self.

autoplasty Adaptation to stress by changing intrapsychic processes. *Compare* alloplasty.

autoscopic psychosis Rare disorder, not officially listed in DSM-5, in which the patient sees a phantom or specter of their own body; usually psychogenic in origin, but may also be caused by lesions in the temporoparietal lobe of the brain.

autotopagnosia Inability to recognize and identify the parts of one's own body. *See also* finger agnosia.

auxiliary therapist Co-therapist. *See also* co-therapy.

average Central value in a frequency distribution around which other values are distributed. Also called the mean.

aversive conditioning AVERSIVE THERAPY.

aversive therapy Behavior therapy that involves the repeated coupling of an unpleasant or painful stimulus, such as an electric shock, with an undesirable behavior pattern in an effort to eliminate the undesirable behavior. Also called aversive conditioning.

avoidance and escape learning In escape learning, an animal learns a response to get out of a place where it does not want to be; for example, it jumps off an electric grid whenever the grid is charged. Avoidance learning requires an additional response: the same animal on the grid will learn to avoid a shock if it quickly pushes a lever when a light signal goes on. Escape learning and avoidance learning are two forms of aversive control using negative reinforcement; behavior that terminates the source of aversive stimuli is strengthened and maintained.

avoidant attachment According to Mary Ainsworth, a form of attachment in which children avoid returning to their mothers after being separated. Also called shyness disorder. *Compare* secure attachment. *See also* resistant attachment.

avoidant disorder of childhood or adolescence Disorder of childhood or adolescence characterized by a persistent withdrawal or excessive shrinking from strangers.

avoidant personality disorder Personality disorder characterized by low self-esteem, hypersensitivity to rejection, and social withdrawal, but with a desire for affection and acceptance.

Avoidant/restrictive food intake disorder Disorder characterized by an avoidance or lack of interest in food, resulting in severe weight loss, nutritional deficiency, and failure to thrive; a DSM-5 diagnosis. Previously called feeding disorder of infancy or early childhood.

axon Single structure in a nerve cell that conducts nervous impulses away from the cell body and its dendrites.

B

barbiturate Any of a class of sedative-hypnotic drugs derived from barbituric acid that acts as a central nervous system depressant and readily produces psychic and physical dependence; for example, phenobarbital, secobarbital, thiopental sodium.

basal ganglia Collectively, the corpus striatum, substantia nigra, subthalamic nucleus, and substantia innominata, which are involved in disorders of movement, thought processes, affect, cognition, and symptoms of psychosis.

basic anxiety As conceptualized by Karen Horney, the main-spring from which neurotic trends get their intensity and pervasiveness, characterized by vague feelings of loneliness, helplessness, and fear of a potentially hostile world. *See also* anxiety.

basic benefits Insurance term that refers to minimum payments or coverage for medical or psychiatric care.

bathophobia Abnormal fear of depths.

battered child syndrome Physical damage to a child sustained as a result of repeated beatings, usually by a parent, parent surrogate, or relative. *See also* abuse.

battery tests Individual tests used together make up a psychological battery; for example, Halstead–Reitan Neuropsychological Battery.

A test battery can give more information about different areas of function than an individual test and can increase the level of confidence if there is a positive correlation between them.

BEAM Brain electrical activity mapping.

Beard, George M. (1839–1883) American psychiatrist who in 1869 introduced the term “neurasthenia.”

Beers, Clifford (1876–1943) Author of *A Mind That Found Itself* (1909) and who is generally considered to have founded the mental hygiene movement.

behavior Sum total of the psyche that includes impulses, motivation, wishes, drives, instincts, and cravings, as expressed by a person’s behavior or motor activity. Also called conation.

behavioral disorders of childhood *See* disruptive behavior disorders.

behavioral medicine Application of principles of behavior therapy to the prevention, diagnosis, treatment, and rehabilitation of medical disorders; applies to such areas as stress prevention and reduction, pediatric and adult patient management and compliance, pain control, and life-style modification. Biofeedback relaxation training, behavior therapy, and hypnosis are important treatment modalities.

behavioral neurology Field of study that attempts to combine psychiatry and neurology to explain abnormal behavior as a disorder of brain metabolism or as a result of structural alterations of the central nervous system.

behavioral science Scientific discipline concerned with any aspect of human behavior, including interpersonal relationships, development, values, experiences, and activities; the behavioral sciences include sociology, psychology, psychiatry, anthropology, and ethology.

behavior contract Therapeutic strategy that rewards a person for a desired behavior.

behaviorism School of psychological thought founded by John B. Watson that regards only measurable and observable behavior as the appropriate subject matter for human psychology; holds that human behavior can be described in terms of principles that do not require consideration of unobservable mental events, such as ideas and emotions. *See also* behavior therapy.

behavior modification *See* behavior therapy.

behavior therapy Psychiatric treatment modality that focuses on overt and objectively observable behavior and uses various conditioning techniques derived from learning theory to directly modify the patient’s behavior; aims exclusively at symptomatic improvement, without addressing psychodynamic causation. Behavior therapy techniques include assertiveness training, aversive therapy, flooding, implosion, reciprocal inhibition, and desensitization, shaping, and systematic desensitization. *See also* behaviorism; conditioning.

Bender-Gestalt Test Psychological test, designed by Lauretta Bender, which measures the subject’s ability to reproduce a set of geometric designs: is useful for measuring visuomotor coordination as a means of detecting brain damage. Also called visual motor gestalt test.

benzodiazepines Any of a group of drugs used mainly to treat anxiety; also used as sedatives, muscle relaxants, anticonvulsants, anesthetics, and hypnotics.

bereavement Feeling of grief or desolation, especially at the death or loss of a loved one. *See also* mourning.

bestiality Sexual deviation in which a person engages in sexual relations with an animal. *See also* zoophilia.

beta (β) error TYPE 2 ERROR.

beta waves As measured by an electroencephalogram (EEG), brainwaves that are between I4 and 30 Hz; altered in certain epileptic conditions.

bias In statistics, an error in the construction of the assessment instrument that favors one outcome over another.

binge eating disorder Eating disorder characterized by recurrent episodic, uncontrolled, compulsive, and rapid ingestions of large amounts of food over a short period of time (binge eating) followed by feelings of guilt; a DSM-5 diagnosis, differentiated from bulimia nervosa by an absence of compulsive compensatory behaviors to achieve weight loss.

binge eating, binge and purge *See* bulimia nervosa.

biodynamics System of psychoanalytic psychiatry, introduced by Jules H. Masserman, which holds that all behavior results from the organism's genetic potentialities, from the various paths and speed of maturation, and from its unique experiences.

biofeedback Provision of information to a person regarding one or more physiologic processes in an effort to enable the person to gain some element of voluntary control over bodily functions that normally operate outside consciousness. *See also* learned autonomic control.

biogenic amine Endogenous compound believed to play an important role in brain function as a central synaptic neurotransmitter substance; biogenic amines include the catecholamines (epinephrine, norepinephrine, dopamine) and serotonin, an indolamine.

biogenic amine hypothesis Theory of mood disorders which proposes that depression is associated with an absolute or relative deficiency of catecholamines, particularly norepinephrine, at functionally important receptor sites in the brain; conversely, elation may be associated with an excess of such amines.

biologic psychiatry School of psychiatric thought emphasizing biochemical, neurologic, and pharmacologic factors in the causation and treatment of psychiatric disorders.

biologic rhythm Periodic variation in physiologic and psychological functions. For example, a circadian rhythm shows aperiodicity of about 24 hours; an ultradian rhythm has a cycle shorter than 1 day; an infradian rhythm is longer than 1 day.

bipolar I Bipolar disorder in which a patient meets the criteria for a full manic episode, usually sufficiently severe to require hospitalization.

bipolar II Bipolar disorder in which a patient has at least one depressive episode and at least one hypomanic episode.

bipolar disorder A mood disorder in which the patient exhibits both manic and depressive episodes separated by various lengths of time. Previously referred to as manic–depressive illness.

birth trauma Otto Rank's term to describe the birth process, which he considered the basic source of anxiety in human beings.

bisexual Denoting or characterized by sexual attraction to and sexual contact with members of both sexes.

bisexuality Existence of the qualities of both sexes in the same person. Freud postulated that the sexes differentiated both biologically and psychologically from a common core; that differentiation between the two sexes was relative, rather than absolute; and that regression to the common core occurs to varying degrees in both normal and abnormal conditions. *Compare* bisexual; heterosexuality; homosexuality. *See also* androgyny.

bizarre delusion False belief that is patently absurd or fantastic.

blackout *See* alcoholic blackout.

black-patch syndrome Psychosis induced by sensory deprivation as a result of eye patches used after cataract surgery.

blank screen Neutral backdrop on which the patient projects a gamut of transferential irrationalities; passivity of analysts allows them to act as blank screens.

Bleuler, Eugen (1857–1939) Swiss psychiatrist known for his important studies in schizophrenia, a term he coined and preferred over the earlier term "dementia praecox."

blind spot In psychiatry, an area of a person's personality of which they are totally unaware; unperceived areas are repressed, since their recognition would arouse painful or unpleasant emotions. In the course of group or individual psychotherapy, such blind spots often appear obliquely as projected ideas, intentions, and emotions. *See also* projection; scotoma.

blocking Involuntary cessation or interruption of thought processes or speech because of unconscious emotional factors. Also called thought deprivation.

Blood–brain barrier Series of biologically active membranes that regulate the passage of substances into and out of the central nervous system; maintains a chemical homeostasis between the cerebrospinal fluid and the venous and arterial systems.

blood level In psychiatry, the measurement of the concentration of drugs in plasma or serum to determine their therapeutic effect.

blunted affect Disturbance of affect manifested by a severe reduction in the intensity of externalized feeling tone; one of the fundamental symptoms of schizophrenia, as outlined by Eugen Bleuler.

board-certified psychiatrist Psychiatrist who has passed the examinations of the American Board of Psychiatry and Neurology (ABPN). *See also* accreditation.

body dysmorphic disorder Disorder characterized by an unrealistic concern that part of the body is deformed. Included on the obsessive-compulsive spectrum in DSM-5. Also called dysmorphophobia.

body-focused repetitive behavior disorders Descriptive term for a group of behaviors consisting of compulsions that damage one's own body, such as skin biting, lip biting, or nail biting; not a diagnosis in DSM-5.

body image Conscious and unconscious perception of one's body at any particular time.

body language Expression of thoughts and feelings by body posture and movement.

bonding Nonsexual feelings of love, respect, and communality among individuals of the same sex. Specifically, a mother's feelings for her infant, but often used to refer to the general mother–infant relationship; fathers often bond to infants. *See also* attachment.

borderline intellectual functioning A term previously attributed to individuals with below-average cognitive ability (IQ in the 70–80 range) whose intellectual impairment did not meet criteria for intellectual disability (IQ below 70). This condition is not clearly differentiated from mild intellectual disability and may be the focus of clinical attention, however, no definitive criteria for diagnosis exist in DSM-5. *See also* intellectual disability.

borderline personality disorder Personality disorder marked by instability in various areas, impulsiveness, suicidal acts, selfmutilations, identity problems, and feelings of emptiness or boredom.

borderline psychosis BORDERLINE STATE.

borderline state State in which the symptoms are so unclear or transient that it is difficult to classify the patient as psychotic or nonpsychotic. Also called borderline psychosis.

boufée délirante A syndrome, observed in West Africa and Haiti, characterized by a sudden outburst of agitated and aggressive behavior, marked confusion, and psychomotor excitement. It is sometimes accompanied by visual or auditory hallucinations or paranoid ideations. May resemble an episode of brief psychotic disorder.

Bowlby, John (1907–1990) British psychoanalyst who formulated the theory of attachment to describing the mother–infant relationship. *See also* attachment; bonding.

bradykinesia Slowness of motor activity, with a decrease in normal spontaneous movement.

bradylalia Abnormally slow speech, common in depression.

bradylexia Inability to read at normal speed.

brain That part of the central nervous system contained within the cranium; includes the cerebrum, midbrain, cerebellum, pons, and medulla.

brain abscess Localized, suppurative, infectious process involving a part of the brain; may produce an organic mental disorder as well as focal neurologic signs.

brain electrical activity mapping (BEAM) Response of brain electrical activity to sensory stimuli which is recorded by computer averaging techniques that produce a topographic color map of brain activity.

brain imaging Radiologic techniques that allow assessment in vivo of structural and functional neuroanatomy; include computed tomography (CT), magnetic resonance imaging (MRI), regional cerebral blood flow (rCBF), positron emission tomography (PET), and brain electrical activity mapping (BEAM).

brain metabolism Chemical changes in the brain that convert small molecules into large ones (anabolism) and large molecules into small ones (catabolism), and that account for cellular function and repair.

brain stem Area of the brain comprising the mesencephalon, pons, and medulla oblongata, whose basic functions concern respiration, cardiovascular activity, sleep, and consciousness; also the site of the ascending biogenic amine (dopamine, noradrenalin, serotonin) pathways to higher brain areas.

brain syndrome *See* organic mental disorder.

brainwashing Any technique designed to manipulate human thought or action against the desire, will, or knowledge of the person involved; usually refers to systematic efforts to indoctrinate nonbelievers. In DSM-5 diagnosed as "identity disturbance due to prolonged and intense coercive persuasion." Also called coercive persuasion.

brain wave Rhythmic wave-like electrical pattern in an encephalogram.

Brawner decision *See* Model Penal Code.

breathing-related sleep disorder Characterized by sleep disruption leading to excessive sleepiness or insomnia caused by a sleep-related breathing disturbance; three types of breathing-related sleep disorders include obstructive sleep apnea, central sleep apnea, and sleep-related hypoventilation.

Breuer, Josef (1842–1925) Viennese physician who collaborated with Freud in studies of cathartic therapy, as reported in *Studies on Hysteria* (1895); he withdrew as Freud proceeded to introduce psychoanalysis, but left important imprints on that discipline, such as the concepts of the primary and secondary processes.

brief psychotherapy Psychotherapy in which the sessions are limited to 10 to 15 in number and during which time attempts to modify behavior occur; used in both individual and group settings.

brief psychotic disorder DSM-5 category for a psychosis of less than 4 weeks' duration, with sudden onset after a major stress. Also called brief reactive psychosis.

brief reactive psychosis *See* brief psychotic disorder.

Brigham, Amariah (1798–1849) One of the founders of the American Psychiatric Association and the first editor of its journal.

Brill, A. A. (1874–1948) First American analyst (1908) who translated several of Freud's more important works, was active in the formation of the New York Psychoanalytic Society (1911), and remained a foremost propagator of psychoanalysis as a lecturer and writer.

Briquet syndrome Alternate term for somatic symptom disorder.

broad affect Normal range (varies both within and among cultures) of the expression of a subjectively experienced feeling state (e.g., euphoria, anger, sadness); normal expression of affect involves variability in facial expression, pitch of voice, and hand and body movements.

Broca aphasia MOTOR APHASIA.

brooding compulsion INTELLECTUALIZATION.

bruxism Grinding or gnashing of the teeth, typically occurring during sleep.

bulimia nervosa Recurrent episodic, uncontrolled, compulsive, and rapid ingestion of large amounts of food over a short period of time (binge eating) followed by self-induced vomiting, use of laxatives or diuretics, fasting, or vigorous exercise in order to prevent weight gain (binge and purge); weight is not severely lowered.

burned-out schizophrenic Chronic schizophrenia characterized by a person who is apathetic and withdrawn, with minimal florid psychotic symptoms but with persistent and often severe schizophrenic thought processes. Also called anergic schizophrenia.

burnout Syndrome of physical or emotional exhaustion considered to be a stress reaction to unrelenting performance and emotional demands stemming from one's occupation; symptoms include impaired work performance, fatigue, insomnia, increased susceptibility to physical illness, and reliance on alcohol (or other substances) with a tendency to escalation into physiologic dependency or possibly suicide.

butyrophenone Any of a class of antipsychotic drugs of which haloperidol (Haldol) is a representative example.

C

C.A. Chronologic age.

cacodemonomania Condition in which patients think they are possessed by a devil or other evil spirit.

caffeine Alkaloid found in coffee, tea, and cola drinks which acts as a psychomotor stimulant; caffeine intoxication results from the excessive ingestion of caffeine.

Canadian Psychiatric Association (CPA) National organization of Canadian psychiatrists whose purpose is to further the development of psychiatric education, research, and practice in Canada.

cannabis *See* marijuana.

canonical correlation Multivariate technique used in statistics for simultaneously finding the relationship of linear combinations of two or more predictors and two or more outcomes.

Capgras syndrome Delusional disorder in which the patient believes that persons in the environment are not their real selves but are doubles imitating the patient or imposters imitating someone else.

capitation Prepayment fee based on a fixed number of persons that covers all health care services.

care and protection proceedings Intervention by a court on behalf of a child when the parents or caretakers provide inadequately for the child’s welfare.

carebaria Sensation of discomfort or pressure in the head.

caregiver 1. Any person involved in the identification, prevention, or treatment of illness or disability. **2.** In child psychiatry, a person who tends to the needs of an infant or child. Also called caretaker.

case-control study Study in which the illness is the dependent variable, already being present for the subject to be identified; such studies are therefore retrospective.

case history study Retrospective study that samples persons with a given disorder.

case register Medical records in central data banks.

castration anxiety Anxiety concerning a fantasied loss of or injury to the genitalia.

castration complex In psychoanalytic theory, a group of unconscious thoughts and motives that are referable to the fear of losing the genitalia, usually as punishment for forbidden sexual desires.

catalepsy Condition in which persons maintain the body position into which they are placed; observed in severe cases of catatonic schizophrenia. Also called waxy flexibility; cerea flexibilitas. *See also* command automatism.

cataphasia VERBIGERATION.

cataplexy Temporary sudden loss of muscle tone, causing weakness and immobilization; can be precipitated by a variety of emotional states, and it is often followed by sleep; commonly seen in narcolepsy.

catastrophic anxiety Anxiety associated with cognitive disorders when patients are aware of their defects in mentation; the anxiety may be overwhelming.

catathymia Situation in which elements in the unconscious are sufficiently affect-laden to produce changes in conscious functioning.

catathymic crisis Suddenly occurring, isolated, and nonrepetitive act that develops from a state of intolerable tension.

catatonia Clinical syndrome consisting of marked behavioral irregularities, which may include motoric excitement or immobility, negativism, stupor, echolalia, or echopraxia. In DSM-5, catatonia may be a stand-alone diagnosis; a feature of schizophrenia; associated with other mood/psychotic disorders; associated with medications or substance use; or due to an underlying medical condition.

catatonic excitement Excited, uncontrollable motor activity seen in catatonic schizophrenia. Patients in catatonic state may suddenly erupt into an excited state and may be violent.

catatonic posturing Voluntary assumption of an inappropriate or bizarre posture, generally maintained for long periods of time. May switch unexpectedly with catatonic excitement.

catatonic rigidity Fixed and sustained motoric position that is resistant to change.

catatonic schizophrenia A rare type of schizophrenia; no longer included in DSM-5. *See* catatonia.

catatonic state State characterized by muscular rigidity and immobility (catatonia), usually associated with schizophrenia.

catatonic stupor Stupor in which patients ordinarily are well aware of their surroundings.

catchment area In psychiatry, a circumscribed geographic area served by a particular community mental health center.

catecholamine Biogenic monoamine containing a catechol group. Norepinephrine, epinephrine, and dopamine are catecholamines with important effects on peripheral and central nervous system activity.

categorical attitude ABSTRACT THINKING.

categorical thought Term introduced by Jean Piaget to refer to abstract thinking. *See also* secondary process.

catharsis Release of ideas, thoughts, and repressed materials from the unconscious, accompanied by an affective emotional response and relief; commonly observed in the course of both individual and group psychotherapy, but can also occur outside therapy. *See also* abreaction; conversational catharsis.

cathexis In psychoanalysis, a conscious or unconscious investment of psychic energy in an idea, a concept, an object, or a person. *Compare* acathexis.

CAT scan Incorrect but commonly used variant of “CT scan.” *See also* computed tomography.

cat’s cry syndrome *See* cri-du-chat syndrome.

Cattell Infant Intelligence Scale Psychological test used to assess general motor and cognitive development in infants aged 3 months to 2 years.

causalgia Burning pain that may be either organic or psychic in origin.

cause–effect relationship Relationship in which one action causes a specific reaction.

causalgia Burning pain that may be organic or psychic in origin.

cenesthesia Change in the normal quality of feeling tone in a part of the body.

central nervous system (CNS) The spinal cord and the brain.

central sleep apnea Dyssomnia characterized by repeated episodes of apnea, shallow breathing, and/or irregular breathing that result from a periodic failure of the central nervous system mechanisms to stimulate breathing. There are three subtypes in DSM-5: idiopathic, Cheyne–Stokes breathing pattern, and comorbid with opioid use. *Compare* obstructive sleep apnea.

cephalalgia Headache.

cerea flexibilitas Condition of a person who can be molded into a position that is then maintained; when an examiner moves the person's limb, the limb feels as if it were made of wax. Also called catalepsy; waxy flexibility. Seen in schizophrenia.

cerebral arteriosclerosis Arteriosclerotic involvement (hardening) of arteries of the brain; may lead to organic mental disorder.

cerebrovascular accident Cerebral hemorrhage, thrombosis, or embolism. Also called stroke; apoplexy.

character Constellation of relatively fixed personality traits and attributes that govern a person's habitual modes of response.

character analysis Psychoanalytic treatment that concentrates on character defenses.

character defense Personality trait that serves an unconscious defensive purpose.

character disorder Pattern of personality characterized by maladaptive, inflexible behavior.

Charcot, Jean M. (1825–1893) French neurologist noted for describing hysteria and treating it by means of hypnosis; Freud based much of his early work on Charcot's pioneering studies in hysteria.

chemical dependence *See* drug dependence.

chemotherapy DRUG THERAPY.

child abuse *See* battered child syndrome.

child analysis Application of psychoanalytic principles to the treatment of the child.

childhood disintegrative disorder A condition defined by marked regression in several functional domains (e.g., intellectual, social, motor, and language skills) after at least 2 years of normal development; diagnosis is typically made in children who are between 3 and 4 years of age. In DSM-5, childhood disintegrative disorder is a subset of autism spectrum disorder.

childhood schizophrenia DSM term for pervasive developmental disorder. *See* autistic spectrum disorder.

child-onset fluency disorder *See* stuttering.

chi square Statistical technique in which variables are categorized in order to determine whether a distribution of scores is due to chance or to experimental factors.

chlorpromazine Aliphatic phenothiazine derivative used primarily as an antipsychotic agent and in the treatment of nausea and vomiting.

cholinergic Relating to nerve fibers, tracts, or pathways in which synaptic transmission is mediated by acetylcholine; for example, parasympathetic nerve fibers and somatic motoneurons; also refers to processes activated by acetylcholine.

chorea Movement disorder characterized by random and involuntary quick, jerky, purposeless movements. *See also* extrapyramidal dyskinesia; Huntington chorea.

chronic fatigue syndrome An illness characterized by 6 months or more of severe, debilitating fatigue, often accompanied by myalgia, headaches, pharyngitis, low-grade fever, cognitive complaints, gastrointestinal symptoms, and tender lymph nodes. The cause is unknown.

chronobiology Study of biologic rhythms that objectively explores and quantifies mechanisms of time structure in biologic systems.

chronologic age (C.A.) *See* intelligence quotient.

chronophobia Fear of time characterized by panic, anxiety, and claustrophobia. Sometimes called prison neurosis, since almost all prisoners are affected by it in some fashion.

circadian rhythm *See* biologic rhythm.

circadian rhythm sleep disorder A set of dyssomnias involving a misalignment between desired and actual sleep periods. Includes delayed sleep phase, jet lag, and work shift.

Circadian Rhythm Sleep–Wake Disorders A group of sleep disorders characterized by disruption in sleep that alters a patient's circadian rhythm and is associated with insomnia or excessive sleepiness. There are six types of circadian rhythm sleep–wake disorders in DSM-5: delayed sleep phase type, advanced sleep phase type, irregular sleep–wake type, non–24-hour sleep–wake type, shift work type, and unspecified type.

circumstantiality Disturbance in the associative thought and speech processes in which a patient digresses into unnecessary details and inappropriate thoughts before communicating the central idea; observed in schizophrenia, obsessional disturbances, and certain cases of dementia. *See also* tangentiality.

civil commitment In statutes governing hospitalization of the mentally ill, a legal term meaning a warrant for imprisonment; as recommended by the American Psychiatric Association and the American Bar Association, "commitment" has been replaced by "hospitalization."

CJD Creutzfeldt–Jakob disease.

claims review Method of peer review consisting of the examination of claims for the reimbursement of treatment after it has been rendered.

clairvoyance Extrasensory perception in which there is an alleged ability to perceive that which is out of sight or cannot be seen.

clang association, clanging Association or speech directed by the sound of a word rather than by its meaning; punning and rhyming may dominate the person's verbal behavior; seen most frequently in schizophrenia or mania.

classical conditioning *See* conditioning.

classic migraine *See* migraine.

claustrophobia Abnormal fear of closed or confining spaces.

client-centered psychotherapy Nondirective form of psychotherapy, originated by Carl Rogers, in which the therapeutic process focuses on the patient's own thinking and feeling which the therapist merely helps to clarify through understanding and empathy; developed as a reaction against the authoritativeness and interpretation of the more traditional psychotherapies.

climacteric Menopause and immediate postmenopausal period in women; sometimes used to refer to the same age period in men.

clinical psychologist Psychologist with additional training and experience in a clinical setting who specializes in evaluation and treatment of mental disorders.

clinical psychology Branch of psychology concerned with the application of psychological principles to the prevention, treatment, and understanding of psychopathology.

clonic convulsion An involuntary, violent muscular contraction or spasm in which the muscles alternately contract and relax. Characteristic phase in grand mal epileptic seizure.

clouding of consciousness Any disturbance of consciousness in which the person is not fully awake, alert, and oriented. Occurs in delirium, dementia, and cognitive disorder.

cluster suicides Suicides that occur together in geographic groups or in temporal association. *See also* copy-cat suicides.

cluttering Disturbance of fluency involving an abnormally rapid rate and erratic rhythm of speech that impedes intelligibility; the affected individual is usually unaware of communicative impairment.

CNS Central nervous system.

cocaine Alkaloid, obtained from leaves of the coca plant, whose systemic effects include striking central nervous system stimulation manifested by garrulousness, restlessness, excitement, and feelings of increased muscular strength and mental capacity; also an effective topical local anesthetic.

coefficient of correlation Statistical term referring to the relation between two sets of paired measurements, correlation coefficients are positive, negative, or curvilinear, depending on whether the variations are in the same direction, the opposite direction, or both directions. They can be computed in a variety of ways, the most common being the product–moment method (r); another method is rank correlation (p). Correlation coefficients are intended to show degree of relation, but they do not imply a causal relationship between variables.

coercive persuasion BRAINWASHING.

coexistent culture Alternative system of values, norms, and patterns for behavior; the group therapy experience often leads to an awareness of other systems as legitimate alternatives to one's own system.

cognition Mental process of knowing and becoming aware; an ego function closely associated with judgment.

cognitive-behavioral therapy (CBT) A form of psychotherapy in which the focus of treatment is on changing the thoughts and behaviors that are related to specific symptoms. The aim of treatment is on symptom reduction and improved functioning.

cognitive development Progressive acquisition of conscious thought and problem-solving abilities that begins in infancy and follows an orderly sequence of more or less discrete stages.

cognitive dissonance Incongruity in a person's beliefs, thoughts, or actions that produces an uncomfortable tension state that the person is motivated to change.

cognitive therapy Structured and directive form of therapy developed by Aaron T. Beck that emphasizes how patients think about themselves and the future; consists of reversing the cognitive triad of negative expression of self, negative expression of future, and negative view of the world.

cognitive triad Belief system described by the psychiatrist Aaron Beck that is present in depressed persons who have a negative view of the self, a negative interpretation of present and past experience, and a negative expectation of the future.

cohesion *See* group cohesion.

cohort Group chosen from a well-defined population; cohort studies provide direct estimates of risk associated with a suspected causal factor.

coitus interruptus Sexual intercourse that is interrupted before the man ejaculates.

cold turkey Abrupt withdrawal from opiates, or any addictive central nervous stimulant, without the benefit of methadone or other drugs; a term originated by drug addicts to describe their chills and consequent goose-flesh. Abstinence-oriented therapeutic communities use this type of detoxification.

collective experience Term coined by S. R. Slavson for the common emotional experiences of a group of people, which, in the setting of group psychotherapy, accelerates the therapeutic process. Identification, mutual support, reduction of ego defenses, sibling transferences, and empathy help integrate the individual member into the group.

collective unconscious Psychic contents outside the realm of awareness that are common to mankind in general. Carl Jung, who introduced the term, believed that the collective unconscious is inherited and derived from the collective experience of the species, that it transcends cultural differences, and that it explains the analogy between ancient mythologic ideas and the primitive projections observed in some patients who have never been exposed to those ideas. Also called objective psyche.

coma State of profound unconsciousness from which a person cannot be roused, with minimal or no detectable responsiveness to stimuli; seen in injury or disease of the brain, in such systemic conditions as diabetic ketoacidosis and uremia, and in intoxications with alcohol and other drugs. Coma may also be seen in severe catatonic states and in hysteria.

coma vigil Coma in which the eyes remain open; typically seen in acute organic mental syndromes associated with systemic infection.

combat fatigue Disabling physical and mental reaction to the stresses of military battle; now called posttraumatic stress disorder.

combined therapy Psychotherapy in which the patient is in both individual and group treatment with the same or two different therapists. In marriage therapy, it is the combination of married couples group therapy with either individual sessions with one spouse or conjoint sessions with the marital pair. *See also* co-therapy.

command automatism Condition closely associated with catalepsy in which suggestions are followed automatically.

command hallucination False perception of orders that a person may feel obliged to obey or unable to resist.

command negativism *See* negativism.

commitment Legal process by which a person is confined to a mental hospital, usually against their will.

common migraine *See* migraine.

communication disorder Term referring to a heterogeneous class of disorders resulting from impairment in the ability to receive, send, process, and comprehend concepts or verbal, nonverbal, and written symbolic systems. Communication disorders consist of language disorders, speech sound disorders, and social (pragmatic) communication disorder.

community *See* therapeutic community.

community mental health center Community or neighborhood mental health facility or a group of affiliated agencies that serve as a locus for the delivery of various services of community psychiatry. *See also* community psychiatry.

community psychiatry Psychiatry focusing on the detection, prevention, and early treatment of mental disorders and social deviance as they develop in the community, rather than as they are perceived and encountered at large centralized psychiatric facilities; particular emphasis is placed on the environmental factors that contribute to mental illness.

compensation Conscious or, usually, unconscious defense mechanism by which a person tries to make up (compensate) for an imagined or real physical or psychological deficiency.

compensation neurosis Neurosis induced by the desire for monetary compensation. It is believed that some persons, after sustaining an injury, develop neurotic symptoms in the hope of monetary gain.

competence Ability to perform or accomplish an action or task that another person of similar background and training, or any human being, could reasonably be expected to perform; mental capacity.

competency to stand trial Ability to be tried in a court of law. A person is competent to stand trial when, at the time of the trial, they (1) understand the nature of the charge and the potential consequences of conviction and (2) is able to assist their attorney in their defense.

competition Literally, the struggle for the possession or use of limited goods, concrete or abstract. In psychiatry, a rivalry that may exist between persons in which gratification for one person largely precludes gratification for the other.

complementarity of interaction Concept of bipersonal and multipersonal psychology in which behavior is viewed as a response to stimulation, and interaction replaces the concept of reaction; each person in an interactive situation plays both a provocative role and a responsive role.

complementary role *See* role.

complex Group of interrelated ideas, mainly unconscious, that have a common emotional tone and strongly influence the person’s attitudes and behavior; introduced by Jung, who called it a feeling-toned idea.

complex partial seizure Epilepsy characterized by recurrent behavioral disturbances. Complex hallucinations or illusions, frequently gustatory or olfactory, often herald the onset of the seizure, which typically involves a state of impaired consciousness resembling a dream (dreamy state) during which paramnestic phenomena, such as déjà vu and jamais vu, are experienced and the patient exhibits repetitive, automatic, or semipurposeful behavior; in rare instances, violent behavior may be prominent. Electroencephalography reveals a localized seizure focus in the temporal lobe. Also called psychomotor epilepsy; temporal lobe epilepsy.

complicated grief/bereavement *See* persistent complex bereavement disorder.

compulsion Uncontrollable, repetitive, and unwanted urge to perform an act; serves as a defense against unacceptable ideas and desires, and failure to perform the act leads to overt anxiety. *See also* obsession.

compulsive personality Personality characterized by rigidity, overconscientiousness, extreme inhibition, inability to relax, and the performance of repetitive patterns of behavior.

computed tomography (CT) Radiologic imaging technique for presenting anatomical features from a cross-sectional plane of the body, generated by computer synthesis of x-ray transmission data obtained from many different directions through the given plane; gray and white matter are indistinguishable on CT scans.

conation That part of a person's mental life concerned with cravings, strivings, motivation, drives, and wishes as expressed through behavior or motor activity.

concordance In studies of twins, the degree of similarity between the two members of each pair with respect to the presence or absence of a particular trait. *Compare* discordance.

concrete operations *See* Piaget, Jean.

concrete thinking Thinking characterized by actual things and events and immediate experience, rather than by abstractions; seen in young children, in those who have lost or never developed the ability to generalize (as in certain organic mental disorder), and in schizophrenic persons. *Compare* abstract thinking.

concussion Immediate and transient impairment of brain function resulting from a head injury; usually, an alteration of consciousness is involved.

condensation Mental process in which one symbol stands for a number of components.

conditioned reinforcer *See* reinforcement.

conditioned response *See* conditioning.

conditioned stimulus *See* conditioning.

conditioning Procedure resulting in the acquisition or learning of more or less permanent changes in behavior. There are two main types of conditioning: **1.** Classical conditioning, in which a neutral stimulus is repeatedly paired with a stimulus (unconditioned stimulus) that naturally elicits a response (unconditioned response) until the neutral stimulus (conditioned stimulus) comes to elicit that response (now the conditioned response) by itself. Also called Pavlovian conditioning and respondent conditioning. **2.** Operant conditioning, a procedure developed by B. F. Skinner in which a spontaneously emitted behavior (operant behavior) is either rewarded (reinforced) or punished and, as a result, then occurs with a frequency that is either increased (in the case of reinforcement) or decreased (in the case of punishment). Also called instrumental conditioning. *See also* behavior therapy.

conditioning therapy *See* behavior therapy.

conditions not attributable to a mental disorder DSM category given to a person who may or may not have a mental disorder but who has a problem which may require intervention by a psychiatrist. Included are marital problem, occupational problem, phase of life or other life circumstance problem, malingering, complicated bereavement, antisocial behavior, academic problem, other interpersonal problem, other specified family circumstance, and noncompliance with medical treatment.

conduct disorder A diagnosis used in child psychiatry to refer to children who show antisocial behavior. Such behavior may occur as part of a group (group type), individually (solitary aggressive type), or both.

confabulation Unconscious filling of gaps in memory by imagining experiences or events that have no basis in fact, commonly seen in organic amnestic syndromes; should be differentiated from lying. *See also* paramnesia.

confidence interval Range of values with a specified probability of including the population mean with a specified level of confidence; typically associated with a certain probability level, for example, the 95% confidence interval has a 95% chance of including the population mean.

confidentiality Ethical principle by which the physician is bound to hold secret all information given to them by the patient. Certain states do not legally recognize confidentiality and can require the physician to divulge such information if needed in a legal proceeding. *See also* privilege.

conflict Mental struggle arising from the clash of opposing impulses, drives, or demands. *See also* extrapsychic conflict; intrapsychic conflict.

conflict-free area Part of one's personality or ego that is well integrated and does not cause any conflicts, symptoms, or displeasures.

confrontation Act of letting a person know where one stands in relationship to that person, what one is experiencing, and how one is perceived. Used in a spirit of deep involvement, this technique is a powerful tool for changing relationships; used as an attempt to destroy another person, it can be harmful. In group and individual therapies, the value of confrontation is likely to be determined by the therapist.

confusion Disturbance of consciousness manifested by a disordered orientation in relation to time, place, or person.

congenital Referring to conditions present at birth, including hereditary conditions and those resulting from prenatal development or the process of birth itself.

conjoint therapy Type of marriage therapy in which a therapist sees the partners together in joint sessions. Also called triadic or triangular therapy (since two patients and one therapist work together). *See also* quadrangular therapy.

conjugal paranoia Paranoia characterized by delusions of jealousy; with no evidence or little evidence, a spouse or lover becomes convinced that their partner is being unfaithful. Also called Othello syndrome.

conscience The part of the self that judges one's own values and performance; often used synonymously with superego.

conscious **1.** One of three divisions of Freud's topographic theory of the mind (the others being the preconscious and the unconscious), referring to that portion of mental functioning within the realm of awareness at all times. **2.** More generally, the state having present knowledge of oneself, one's acts, and one's surroundings and thus a functioning sensorium. **3.** Denoting a state of awareness, with response to external stimuli.

consciousness State of awareness, with response to external stimuli. *See also* sensorium.

consensual validation Continuous comparison of the thoughts and feelings of group members toward one another that tends to modify and correct interpersonal distortions; introduced by Harry Stack Sullivan to refer to the dyadic therapeutic process between doctor and patient.

conservation According to Piaget, the crucial difference between preoperational and concrete operational thought, in which a child discovers which values remain invariant in the course of any kind of change or transformation.

conservator Legal guardian designated to take over and protect the interests of an individual.

constipation Inability to defecate or difficulty in defecating.

constitution One's intrinsic psychological or physical endowment. Broadly, it includes an aggregate of characteristics that have developed from the interaction of hereditary and environmental influences; more narrowly, it indicates characteristics that are purely hereditary or genetically determined.

constitutional types Categories of a person's traits based on physical and psychological characteristics (e.g., ectomorphic, endomorphic, mesomorphic).

constricted affect Reduction in intensity of feeling; tone less severe than that of blunted affect but clearly reduced.

constructional apraxia Inability to copy a drawing, such as a cube, clock, or pentagon, as a result of a brain lesion.

Consultation–liaison psychiatry Clinical psychiatry carried out in the medical or surgical wards of a general hospital; the psychiatrist collaborates closely with nonpsychiatric physicians in the total care of the patient.

contagion Force that operates in large groups or masses. When the level of psychological functioning has been lowered, some sudden upsurge of anxiety can spread through a group, accelerated by high degree of suggestibility, gradually mounting to panic, and the whole group may be simultaneously affected by a primitive emotional upheaval.

content thought disorder Disturbance in thinking in which a person exhibits delusions that may be multiple, fragmented, and bizarre.

continuous reinforcement A schedule of reinforcement in which reward is administered every time a response is emitted.

contract Explicit, bilateral commitment to a well-defined course of action; in group or individual therapy, the therapist–patient contract is to attain the treatment goal.

control group In an experimental design, the group in which a condition or factor being tested is deliberately omitted; for example, in a study measuring the effects of a new drug, the control group may be given a placebo instead of the drug. *Compare* experimental group.

controlled substance Drug that has the potential to be abused and is classified by the Drug Enforcement Administration (DEA) into one of five levels of control: I, high abuse potential and no accepted medical use (e.g., heroin); II, high abuse potential with medical use (e.g., amphetamine); III, moderate abuse potential (e.g., codeine); IV, low abuse potential, that is, preparations containing limited amounts of narcotic and nonnarcotic ingredients (e.g., cough medicines).

controlling Excessive attempt to manage or regulate events or objects in the environment to minimize anxiety and to resolve inner conflicts.

conversational catharsis Release of repressed or suppressed thoughts and feelings in group and individual psychotherapy as a result of verbal interchange. *See also* abreaction; catharsis.

conversion Unconscious defense mechanism by which the anxiety that stems from an intrapsychic conflict is converted and expressed in a symbolic somatic symptom; the hallmark of conversion disorder, but also seen in a variety of mental disorders.

conversion disorder Alternate term for functional neurologic symptom disorder.

conversion phenomena The development of symbolic physical symptoms and distortions involving the voluntary muscles or special sense organs; not under voluntary control and not explained by any physical disorder. Most common in conversion disorder, but also seen in a variety of mental disorders.

convulsion An involuntary, violent muscular contraction or spasm. *See also* clonic convulsion; tonic convulsion.

convulsive disorder *See* epilepsy.

convulsive therapy Psychiatric treatment involving administration of chemical substances or electric current to induce loss of consciousness or a convulsive reaction, to alter favorably the course of a mental disorder; for example, electroconvulsive therapy, insulin coma therapy.

cooperative therapy CO-THERAPY.

coping mechanism Unconscious or conscious way of dealing with stress.

coprolalia Involuntary use of vulgar or obscene language; observed in some cases of schizophrenia and in Tourette syndrome.

coprophagia Eating of filth or feces.

coprophilia Excessive interest in filth or feces. Sexual pleasure associated with feces is a perversion associated with fixations at the anal stage of psychosexual development.

coprophobia Abnormal fear of excreta.

copy-cat suicides Suicides that occur in persons who are geographically related; usually occurs among adolescents within a limited time period. *See also* cluster suicides.

correctional psychiatry Practice of psychiatry on persons incarcerated in jail or prison; presents special problems in relation to confidentiality and countertransference.

corrective emotional experience Re-exposure under favorable circumstances to an emotional situation that the patient could not handle in the past; as advocated by Franz Alexander, the therapist temporarily assumes a particular role to generate the experience and facilitate reality testing.

correlation Statistical index of the relationship among variables. The most common correlation coefficient is the Pearson Product

Moment Correlation, an index of bivariate association that varies between >1.0 and 1.0. *See also* coefficient of correlation.

Cotard syndrome *See* nihilistic delusional disorder.

co-therapy Psychotherapy in which more than one therapist treat the individual patient or the group. Also called cooperative, dual, multiple, or three-cornered therapy. *See also* combined therapy.

counseling Form of guidance in which a trained person offers advice or education about specific problems in living, for example, marriage, child rearing, mourning.

counterphobia State in which a phobic person shows a preference for the very situation that is feared.

countertransference Conscious or unconscious emotional response of the therapist to the patient; determined by the therapist's inner needs, rather than by the patient's needs, and may reinforce the patient's earlier traumatic history if not checked by the therapist. *See also* transference.

couples therapy *See* family therapy; marriage therapy.

covert sensitization Method of reducing the frequency of behavior by associating it with the imagination of an unpleasant consequence.

CPA Canadian Psychiatric Association.

crack Freebase form of cocaine prepared by heating a mixture of cocaine hydrochloride, water, and baking soda, which is then dried into a solid and broken into small pieces (rocks); it is inexpensive, has a rapid onset of action, and is highly addictive.

creativity Ability to produce something new. Silvano Arieti described creativity as the tertiary process, a balanced combination of primary and secondary processes, in which materials from the id are used in the service of the ego.

cretinism Mental and physical retardation resulting from severe thyroid deficiency in infancy and childhood.

Creutzfeldt–Jakob disease (CJD) A rapidly progressive, invariably fatal disorder that occurs mainly in middle-aged or older adults. It initially manifests with fatigue, flu-like symptoms, and cognitive impairment; as it progresses, focal neurologic findings such as aphasia and apraxia occur. Psychiatric symptoms include anxiety, euphoria, depression, delusions, hallucinations, or marked personality changes. Progresses over months and leads to dementia, akinetic mutism, coma, and death.

Cri-du-chat High-pitched catlike cry characteristic of the syndrome of mental and physical retardation caused by partial deletion of chromosome 5. Also called cat's cry syndrome.

criminal responsibility Legal term meaning the ability to formulate a criminal intent at the time of an alleged crime. A person cannot be convicted of a crime if it can be proved that they lacked criminal responsibility by reason of insanity.

crisis In psychiatry, a distressing sense of psychological disequilibrium that has an acute onset and that causes impaired functioning in a variety of interpersonal and vocational areas.

crisis intervention Brief therapeutic approach used in emergency rooms of general or psychiatric hospitals that is ameliorative, rather than curative, of acute psychiatric emergencies; treatment factors often focus on environmental modification, although interpersonal and intrapsychic factors are also considered. *See also* hot line.

critical period Specific period of early development during which an organism acquires certain patterns of behavior as a result of internal or external clues. *See also* imprinting.

critical ratio In a statistical study involving 30 or more subjects, a ratio constructed to determine whether differences found between two items are larger than could be expected from chance alone.

cross-cultural psychiatry Comparative study of mental illness and health among various societies around the world.

cryptographia A private written language.

cryptolalia A private spoken language.

CT scan Computed tomography.

cult System of beliefs and rituals, especially involving devoted attachment to or extravagant admiration of a person or principle, based on dogma or religious teachings; devoted adherents to such a system are called cultists.

cultural anthropology *See* anthropology.

cultural deprivation Restricted participation in the culture of the larger society.

cultural psychiatry Branch of psychiatry concerned with mental illness in relation to the cultural environment; symptoms regarded as psychopathologic in one cultural setting may be acceptable and normal in another.

culture shock Psychological response of a person who is suddenly thrust into an alien culture or has divided loyalties to two different cultures.

culture specific syndrome Disorder of behavior that occurs within or is limited to a specific culture; for example, amok, koro, latah.

cunnilingus Use of the mouth or tongue to stimulate the female genitalia.

Cushing syndrome Hyperadrenocorticism characterized by muscle wasting, obesity, osteoporosis, atrophy of the skin, and hypertension; emotional lability is common and frank psychoses are occasionally observed.

custody Term used to describe a parent's legal rights over a child; in cases of disputed custody, the child is awarded to the party who will best serve the interests of the child.

CVA Cerebral vascular accident.

cybernetics Norbert Wiener's term for the comparative study of computers and the human nervous system.

cybersex addiction A paraphilia characterized by dependence on the internet for sexual gratification (e.g., internet pornography, sex-chat rooms).

cyclazocine Narcotic antagonist that blocks the effects of morphine and heroin.

cycloplegia Paralysis of the muscles of accommodation in the eye; observed at times as an autonomic side effect (anticholinergic effect) of antipsychotic or antidepressant medication.

cyclothymia Mood disorder characterized by a nonpsychotic disturbance of at least 2 years length with numerous periods of both depressive and manic syndromes not severe enough to be classified as depressive or manic episodes.

cyclothymic disorder Mood disorder characterized by a nonpsychotic disturbance of at least 2 years' length with numerous periods of both depressive and hypomanic syndromes that are not severe enough to be classified as depressive or hypomanic episodes.

cynophobia Abnormal fear of dogs.

D

Da Costa syndrome Chest pain, palpitations, and lightheadedness occurring as a somatic manifestation of pathologic anxiety. Also called neurocirculatory asthenia; soldier's heart.

day hospital Form of partial hospitalization in which a patient spends the day in the hospital and returns home at night. *Compare* night hospital; weekend hospital.

day residue In Sigmund Freud's dream theory, the content of the dream imagery that is derived from events of the previous day.

DEA Drug Enforcement Administration.

death instinct AGGRESSIVE DRIVE.

decathexis ACATHEXIS.

decision tree algorithm.

de Clérambault syndrome *See* erotomania.

decoding Technical term for the process of understanding spoken language.

decompensation Deterioration of psychic functioning due to a breakdown of defense mechanisms.

decomposition In psychiatry, the division of a person into separate personalities or identities, as seen in the paranoid schizophrenic person who splits the persecutor into separate entities.

deep brain stimulation A wired electrode with multiple stimulating sites that is surgically implanted into the brain chronically administers electrical stimulation. Use to treat tremor in Parkinson disease.

defense mechanism Unconscious process acting to relieve conflict and anxiety arising from one's impulses and drives.

defensive emotion Strong feeling that serves as a screen for a less acceptable feeling, one that would cause a person to experience anxiety if it appeared. For example, expressing the emotion of anger is often more acceptable to a patient than expressing the fear that the anger covers up; in that instance, anger is defensive.

deficit In psychiatry, the absence of a function or capability that would normally be present, for example, judgment.

deinstitutionalization Discharge from the hospital to community, particularly of those chronically mentally ill patients who would otherwise be hospitalized for long periods of time.

déjà entendu Illusion that what one is hearing one has heard previously. *See also* paramnesia.

déjà pensè Condition in which a thought never entertained before is incorrectly regarded as a repetition of a previous thought.

déjà vu Illusion of visual recognition in which a new situation is incorrectly regarded as a repetition of a previous experience. *See also* paramnesia.

delayed ejaculation DSM-5 term for male orgasmic disorder.

delayed sleep phase circadian rhythm disorder A circadian rhythm sleep–wake disorder characterized by sleep–wake times that are later than conventional times; individuals with this disorder are referred to as “night owls.”

delirium Acute reversible organic mental disorder characterized by confusion and some impairment of consciousness; generally associated with emotional lability, hallucinations or illusions, and inappropriate, impulsive, irrational, or violent behavior.

delirium tremens (DTs) Acute and sometimes fatal reaction to withdrawal from alcohol, usually occurring 72 to 96 hours after the cessation of heavy drinking; distinctive characteristics are marked autonomic hyperactivity (tachycardia, fever, hyperhidrosis, dilated pupils), usually accompanied by tremulousness, hallucinations, illusions, and delusions. Called alcohol withdrawal delirium in DSM. *See also* formication.

delta sleep SLOW WAVE SLEEP.

delta waves As measured by an electroencephalogram (EEG), brain waves that are less than 4 Hz, indicative of deep sleep.

delusion False belief that is firmly held, despite objective and obvious contradictory proof or evidence and despite the fact that other members of the culture do not share the belief. Types of delusion include: **bizarre delusion,** one that is patently absurd or fantastic; **delusion of control,** that a person's thoughts, feelings, or actions are not one's own but are being imposed by some external force; **delusion of grandeur (grandiose delusion),** exaggerated concept of one's importance, power, knowledge, or identity; **delusion of jealousy (delusion of infidelity),** that one's lover is unfaithful; **delusion of persecution,** that one is being attacked, harassed, cheated, or conspired against; **delusion of poverty,** that one is or will be without material possessions; **delusion of reference,** that events, objects, or the behavior of others have a particular and unusual meaning specifically for oneself; **encapsulated delusion,** one without significant effect on behavior; fragmentary delusion, poorly elaborated delusion, often one of many with no apparent interconnection; **nihilistic delusion, delusion of negation** (Cotard syndrome), that the world and everything related to it have ceased to exist; **paranoid delusion,** combined delusion of grandeur and persecution; **religious delusion,** one involving the Deity or theologic themes; **sexual delusion,** one centering on sexual identity, appearances, practices, or ideas; **somatic delusion,** pertaining to the functioning of one's body; **systematized delusion,** a group of elaborate delusions related to a single event or theme.

delusional depression Depressive disorder characterized by false, fixed ideas, that is, delusions; listed in DSM as major depression, severe, with psychotic features.

delusional (paranoid) disorder Psychotic disorder in which there are persistent delusions (e.g., erotomanic, grandiose, jealous, persecutory, somatic, mixed, and unspecified); symptoms of a major mood disorder are absent, and the delusions lack the bizarre quality often seen in schizophrenia.

dementia Mental disorder characterized by general impairment in intellectual functioning, frequently characterized by failing memory, difficulty with calculations, distractibility, alterations in mood and affect, impairment in judgment and abstraction, reduced facility with language, and disturbance of orientation. Although generally irreversible because of underlying progressive, degenerative brain disease, dementia may be reversible if the cause can be treated. Called major neurocognitive disorder in DSM-5. *Compare* amentia.

dementia associated with alcoholism DSM term for alcoholic deterioration.

dementia of the Alzheimer type Term for a clinical disorder in an older adult patient characterized by a severe loss of intellectual function, for which no other cause is found, and that is progressive and insidious and marked by disorientation as to time, place, and person; senile onset is after age 65 (senile dementia); presenile onset is before age 65 (presenile dementia). Also called Alzheimer disease. *See also* Pick disease.

dementia praecox (precox) Obsolete term for schizophrenia.

demography Statistical study of populations, including births, marriages, mortality, health, geographic distribution, and population shifts.

demophobia Abnormal fear of crowds.

dendrite Projection from the nerve cell body, usually profusely branched and studded with small spikes (dendritic spines) that are the sites of synaptic connection; most dendrites receive neurotransmissions from an axon.

denial Defense mechanism in which the existence of unpleasant realities is disavowed; refers to a keeping out of conscious awareness any aspects of either internal or external reality that, if acknowledged, would produce anxiety.

dependence on therapy Pathologic need of a patient for therapy, created out of the belief that one cannot survive without it.

dependency State of reliance on another, as for security, love, protection, or mothering.

dependent personality disorder Personality disorder characterized by lack of self-confidence, a tendency to have others assume responsibility for significant areas of one's life, and a subordination of one's own needs and wishes to those of the others on whom one is dependent; solitude is extremely discomforting.

dependent variable In research methodology, those qualities that measure the influence of the independent variable or the outcome of the experiment; for example, measurement of a person's specific physiologic reactions to a drug. Also called outcome variable.

depersonalization Called depersonalization disorder in DSM-5, a disordered sensation of unreality concerning oneself, parts of oneself, or one's environment that occurs under extreme stress or fatigue. Seen also in schizophrenia and schizotypal disorder.

depersonalization disorder [Omit entry.]

depression Mental state characterized by feelings of sadness, loneliness, despair, low self-esteem, and self-reproach; accompanying signs include psychomotor retardation or at times agitation, withdrawal from interpersonal contact, and vegetative symptoms such as insomnia and anorexia. The term refers either to a mood that is so characterized or to a mood disorder.

depressive neurosis DYSTHYMIA.

depth psychology Psychology that focuses on unconscious processes, rather than conscious processes.

derailment Gradual or sudden deviation in train of thought without blocking; sometimes used synonymously with loosening of association.

derealization Called derealization disorder in DSM-5, disordered sensation of a changed reality or that one's surroundings have altered; also seen in schizophrenia.

dereism Mental activity that follows a totally subjective and idiosyncratic system of logic and fails to take the facts of reality or experience into consideration. *See also* autistic thinking.

dereistic thinking Mental activity not concordant with logic or experience.

descriptive psychiatry System of psychiatry focusing primarily on the study of observable symptoms and behavioral phenomena, rather than underlying psychodynamic processes; Emil Kraepelin's systematic description of mental illness was an early example. *See also* dynamic psychiatry.

descriptive statistics Methods used to summarize, organize, and describe observations; for example, the mean, standard deviation, and variance.

desensitization *See* systematic desensitization.

designer drug Any version of a regulated drug whose chemical structure has been modified so that it falls outside the restrictions placed on the regulated drug it imitates; usually a drug of abuse used to alter states of consciousness or to produce pleasurable feelings.

detachment A state of being in which the person is separated or divorced from emotional involvement with others, characterized by distant interpersonal relationships.

determinism Concept that nothing occurs by chance alone; instead, things result from specific causes or forces. This school of thought denies the notion of free will.

detoxification Any treatment aimed at the restoration of normal physiologic function after a disturbance by the use of some drug or chemical substance. *See also* cold turkey.

detumescence Subsiding of a penile erection; also used to describe the subsiding of genital engorgement in both sexes.

devaluation Defense mechanism in which a person attributes excessively negative qualities to self or others. Seen in depression and paranoid personality disorder.

developmental arithmetic disorder Academic skills disorder characterized by marked impairment in the development of arithmetic skills that interferes with academic achievement or other activities of daily living. Also called acalculia; Gerstmann–Straussler–Scheinker disease, congenital arithmetic disability; dyscalculia; arithmetic disorder.

developmental articulation disorder *See* speech sound disorder.

developmental coordination disorder Motor skills disorder of childhood with significant impairment in the development of fine or gross motor coordination that interferes with academic achievement or with activities of daily life.

developmental disorders Disorders originating in infancy and childhood that continue in adulthood and which interfere with the person’s ability to function normally. In DSM, called neurodevelopmental disorders and include intellectual developmental disorder (formally known as mental retardation) and autistic spectrum disorders.

developmental expressive language disorder Language and speech disorder in which there is marked impairment in the development of expressive language; interferes with academic achievement or with activity of daily living that require the expression of verbal (or sign) language.

developmental expressive writing disorder Academic skills disorder characterized by marked impairment in the development of expressive writing skills; significantly interferes with academic achievement or with activities of daily living that require expressive writing skills.

developmental reading disorder Academic skills disorder characterized by omissions, distortions, and substitutions of words and by slow, halting reading; there is marked impairment in the development of words recognition skills and reading comprehension. Also called specific reading disability and developmental word blindness.

developmental receptive language disorder Language and speech disorder in which there is marked impairment in the development of language comprehension which significantly interferes with academic achievement or with activities of daily living that require comprehension of verbal (or sign) language.

developmental word blindness DEVELOPMENTAL READING DISORDER.

deviation Departure from the average or norm.

Dexamethasone Suppression Test (DST) Test used to confirm a diagnostic impression of major depression. The patient is given 1 mg of dexamethasone (a long-acting synthetic glucocorticoid) by mouth at 11 PM, and plasma cortisol is measured at 8 AM, 4 PM, and

11 PM. Plasma cortisol above 5 μg/dL (nonsuppression) is considered abnormal, that is, positive; suppression of cortisol indicates that the hypothalamic–adrenal–pituitary axis is functioning properly.

***Diagnostic and Statistical Manual of Mental Disorders* (DSM)** Handbook for the classification of mental illnesses that is primarily descriptive and does not describe the theories or causes of disorders; first issued by the American Psychiatric Association in 1952 (DSM-I). The fourth edition (DSM-IV) was issued in 1994 and the text revision of fourth edition (DSM-IV-TR) was published in 2000. The DSM-5 was published in 2013 and its text revision (DSM-5-TR) was published in 2022.

dialectical behavior therapy (DBT) A form of therapy used for patients with borderline personality disorder and parasuicidal behavior that is eclectic using advice-giving, cognitive training, story-telling, and confrontation among many other techniques.

diathesis-stress paradigm In psychopathology, a view that abnormal behavior is a function of a series of stresses in predisposed individuals (due to hereditary, temperamental, and sociocultural factors).

differential diagnosis Determination of which of two or more diseases with similar symptoms is the one that afflicts the patient.

differential reinforcement Procedure in which desirable behavior is reinforced and problematic or less desirable behavior is extinguished or punished.

differentiation First of Margaret Mahler’s four subphases of the separation–individuation process, occurring from ages 5 to 10 months, when the child is able to distinguish between self and other objects.

2,5-dimethoxy-4-methylamphetamine (DOM) Synthetic (derivative) drug with hallucinogenic properties. Also colloquially called STP.

dimethyltryptamine (DMT) Tryptamine congener that acts as a psychedelic capable of producing hallucinations, other disorders of perception, and altered moods and states of consciousness.

diminished libido Decreased sexual interest and drive.

dipsomania An obsolete term that refers to the compulsion to drink alcoholic beverages.

disability Defined by the federal government as: "Inability to engage in any substantial gainful activity by reason of any medically determinable physical or mental impairment which can be expected to last or has lasted for a continuous period of not less than 12 full months."

disconnection syndrome Group of neurologic disorders produced after interruption of connection fibers from the cerebrum to other centers of the nervous system.

discontinuation syndrome Signs and symptoms that occur when a person stops taking a drug either suddenly or gradually when the drug previously has caused physical or psychological dependence to occur. Also called abstinence syndrome; withdrawal syndrome.

discordance In studies of twins, the degree of dissimilarity between the two members of each pair with respect to the presence or absence of a particular trait. *Compare* concordance.

discriminant analysis Multivariate method for finding the relationship between a single discrete outcome and a linear combination of two or more predictors.

discrimination Process of distinguishing between different but often similar stimuli and reacting appropriately; more specifically, the occurrence of operant behavior in environments in which the behavior has been reinforced but not in those in which it has not been reinforced. *See also* discriminative stimulus.

discriminative stimulus Environmental event correlating with the operation of a certain reinforcement matrix, such that behavior that has been reinforced in the presence of the stimulus but not in its absence tends to occur only when the stimulus is present.

disinhibition 1. Removal of an inhibitory effect, as in the reduction of the inhibitory function of the cerebral cortex by alcohol. **2.** In psychiatry, a greater freedom to act in accordance with inner drives or feelings and with less regard for restraints dictated by cultural norms or one's superego.

disinhibited social engagement disorder A disorder of markedly disturbed social relatedness in which a child approaches and interacts with unfamiliar adults in an overly familiar manner; presumed to result from grossly pathologic care-giving.

disintegration Psychic disorganization in which a person is unable to recognize reality and may develop delusions, hallucinations, or overwhelming anxiety and panic.

disorder of written expression A learning disorder characterized by writing skills that are significantly below the expected level for a child's age and intellectual capacity.

disorders of excessive somnolence Disorders characterized by excessive amounts of sleep or excessive daytime sleepiness. *See also* somnolence.

disorders of initiating and maintaining sleep Disorders characterized by inability to fall asleep or repeated awakening after failing asleep. *See also* insomnia disorder; dyssomnias.

disorganized schizophrenia Type of schizophrenia characterized by markedly disinhibited and aimless, nonconstructive behavior; no longer included in DSM-5.

disorientation Confusion; impairment of awareness of time, place, and person (the position of the self in relation to other persons); characteristic of cognitive disorders.

displacement Unconscious defense mechanism by which the emotional component of an unacceptable idea or object is transferred to a more acceptable one. Seen in phobias.

disposition Sum total of a person's inclinations as determined by their mood.

disruptive behavior disorders Disorders characterized by inattention, overagressiveness, delinquency, destructiveness, hostility, feelings of rejection, negativism, or impulsiveness. In DSM, they include attention-deficit hyperactivity disorder, conduct disorder, and oppositional defiant disorder.

disruptive mood dysregulation disorder A depressive disorder in individuals between 6 and 18 years of age that is characterized by chronic irritability, severe temper tantrums, and angry mood; a DSM-5 diagnosis.

dissociation Unconscious defense mechanism involving the segregation of any group of mental or behavioral processes from the rest of the person’s psychic activity; may entail the separation of an idea from its accompanying emotional tone, as seen in dissociative and conversion disorders.

dissociation syndrome Functional inability of the brain to process information from one area to another; first described by neurologist Norman Geschwind. *See also* disconnection syndrome.

dissociative amnesia Disorder characterized by memory loss of important autobiographical information that is usually stressful or traumatic in nature.

dissociative disorders Mental disorders characterized by a sudden temporary alteration in consciousness, identity, or motor behavior. In DSM, they include dissociative amnesia, dissociative fugue, dissociative identity disorder, and depersonalization disorder. *See also* hysteria.

dissociative identity disorder Dissociative reaction in which a person has two or more distinct personalities, most of them knowing nothing of the others; a DSM-5 diagnosis. Previously called multiple personality disorder.

dissociative trance disorder Disorder characterized by temporary alteration in the state of consciousness or personal identity without replacement by an alternate identity; may occur during the course of a psychotic disorder or result from substance use. Not a DSM diagnosis.

distortion 1. Misrepresentation of reality. **2.** In psychoanalysis, the process of modifying unacceptable unconscious mental elements so that they are allowed to enter consciousness in a more acceptable but disguised form.

distractibility Inability to focus one’s attention; the patient does not respond to the task at hand but attends to irrelevant phenomena in the environment.

distractible speech Pattern of speech in which a person changes subjects in response to nearby stimuli.

distributive analysis and synthesis Therapeutic application of Adolf Meyer’s psychobiologic school of psychiatry; systematic investigations of patients’ entire past experiences yield constructive syntheses of their assets and liabilities and lead to an effort to enable them to adapt to their environment.

disulfiram Drug used in the treatment of alcoholics. By altering the metabolism of alcohol, it produces unpleasant physical sensations that discourage the patient from further consumption of alcohol (trade name, Antabuse).

Dix, Dorothea Lynde (1802–1887) Former schoolteacher who became a prominent advocate for the indigent mentally ill. Her efforts helped create the first generation of American mental asylums in improving the humane treatment of the mentally ill.

dizygotic twins Twins (fraternal) who develop from two separately fertilized ova; in contrast, monozygotic (identical) twins develop from a single fertilized ovum.

DMT Dimethyltryptamine.

Doctor–patient relationship Human interchange that exists between the person who is sick and the person who is selected to heal because of training and experience.

DOES Disorders of excessive somnolence.

DOM 2,5-Dimethoxy-4-methylamphetamine.

dominance **1.** Disposition to play a commanding, controlling, or prevailing role over others. **2.** In neurology, the control of language function by one side of the cerebral cortex. **3.** In genetics, the ability of a gene (dominant gene) to be expressed in the phenotype of the bearer to the exclusion of another gene (recessive gene) with which it is paired.

dopamine Biogenic amine (catecholamine) that inhibits prolactin; functional integrity of the dopaminergic system is impaired in depression and in Parkinson disease.

dopamine hypothesis Theory that there may be an excess of dopamine in the brains of persons with schizophrenia.

dopamine-receptor agonists Drugs that activate dopamine receptors in the absence of dopamine. Commonly used in the treatment of Parkinson disease.

dopamine-receptor antagonists (DRAs) Drugs that block the receptors for dopamine in the brain. Also known as first-generation or typical antipsychotics. *Compare* serotonin-dopamine antagonists.

double bind As formulated by Gregory Bateson, a situation involving the simultaneous communication of conflicting messages from one person to another, in which the response to either message is met with disapproval or rejection; believed to be a characteristic mode of interaction in some families with a schizophrenic member.

double-blind study Study in which, for example, one or more drugs and a placebo are compared in such a way that neither the patient nor the persons directly or indirectly involved in the study know which is being given to the patient; the drugs being investigated and the placebo are coded for identification.

double depression A mood disorder that occurs when the criteria for major depressive disorder and dysthymia are met simultaneously.

double personality *See* multiple personality disorder.

Down syndrome Syndrome of mental retardation associated with a variety of abnormalities caused by replication of chromosome 21 three times. Also called trisomy 21 syndrome. Formerly called mongolism.

DRA Dopamine-receptor antagonist.

Draw-A-Person (DAP) Test Easily administered test used with both children and adults, usually with the instructions, “I’d like you to draw a picture of a person; draw the best person you can.” A general assumption is that the drawing of a person represents the expression of the self or of the body in the environment.

drawing test Any of a variety of psychological tests in which the subject is asked to draw certain familiar objects, such as people, trees, and houses; attitudes and feelings are often revealed in the way the subject depicts those objects.

dread Massive or pervasive anxiety, usually related to a specific danger.

dream Mental activity during sleep in which thoughts, emotions, and images are experienced as though real; associated with rapid eye movement (REM) sleep. Dreams were regarded by Freud as providing an outlet for the discharge in disguised form of unconscious and often unacceptable impulses and wishes.

dream anxiety disorder *See* nightmare disorder.

dreamy state Altered state of consciousness, likened to a dream situation, that develops suddenly and from which the patient usually recovers within a few minutes; accompanied by visual, auditory, and olfactory hallucinations and most commonly associated with temporal lobe lesions.

drive Hypothetical construct used to explain motivated behavior: a basic urge that produces a state of psychic tension that motivates the person into action to alleviate the tension; currently preferred over Freud’s term “instinct.” *See also* aggressive drive; sexual drive.

drowsiness State of impaired awareness associated with a desire or inclination to sleep.

drug abuse Use of any drug, usually by self-administration, in a manner that deviates from approved social or medical patterns.

drug dependence Habituation or addiction to the use of a drug or chemical substance, with or without physical dependence; physical dependence indicates an altered physiologic state due to repeated administrations of a drug, the cessation of which results in the appearance of a withdrawal or abstinence syndrome characteristic for the particular drug which is called discontinuation syndrome.

Drug Enforcement Administration (DEA) Agency of the federal government that regulates distribution of controlled substances such as opioids, barbiturates, and other drugs of potential abuse.

drug holiday Limited period of time during which the administration of a psychoactive drug is discontinued in order to control dosage and side effects or to evaluate baseline behavior.

drug-induced parkinsonism PSEUDOPARKINSONISM.

drug interaction Effect that one drug has on the actions of one or more other drugs given at the same time; effects of either drug may be increased, diminished, or inactivated as a result of the interaction.

drug levels Blood serum or plasma level of psychotropic drugs. *See also* pharmacokinetics.

drug therapy Use of chemical substances in the treatment of a disease or disorder. Also called chemotherapy.

drug tolerance *See* tolerance.

DSM *Diagnostic and Statistical Manual of Mental Disorders.*

DST Dexamethasone Suppression Test.

DTs Delirium tremens.

dual-sex therapy Specific form of psychotherapy developed by William Masters and Virginia Johnson in which treatment is focused on a particular sexual disorder. The crux of the program is the round-table session, in which both a male therapist and a female therapist are present with the patient couple; special exercises are prescribed for the couple, the overall goal being to diminish fears of sexual performance and to facilitate communication in sexual and nonsexual areas.

dual therapy CO-THERAPY.

dummy Uncommonly used term for placebo; for example, dummy drug.

Durham rule Federal court ruling in 1954 holding that “an accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect.” It has since been replaced by the American Law Institute formulation of insanity, which states that “a person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or defect he lacks substantial capacity either to appreciate the wrongfulness of his conduct or to conform his conduct to the requirements of law.” *See also* M’Naghten rule.

dyad Pair of persons in an interactional situation, such as husband and wife, mother and father, co-therapists, or patient and therapist.

dyadic session Psychotherapeutic session involving only two persons, the therapist and the patient.

dynamic psychiatry System of psychiatry concerned with the mental mechanisms and emotional processes that govern and motivate human behavior, in contradistinction to descriptive psychiatry, which focuses on observable behavioral phenomena.

dynamic reasoning Franz Alexander's term for the formation of all the clinical evidence gained from free-associative anamnesis into a psychological reconstruction of the patient's development.

dynamics *See* psychodynamics.

dysarthria Impairment of articulation, the motor activity of shaping phonated sounds into speech.

dyscalculia Difficulty in performing calculations.

dysdiadochokinesis *See* adibdochokinesis.

dysgeusia Impairment of the sense of taste.

dysgraphia Difficulty in writing.

dyskinesia Any disturbance of movement, as in extrapyramidal dyskinesia.

dyslalia Faulty articulation due to structural abnormalities of the articulatory organs or impaired hearing.

dyslexia A specific learning disability syndrome involving an impairment of the ability to read; unrelated to the person's intelligence. *Compare* alexia.

dysmetria Impaired ability to gauge distance relative to bodily movements.

dysmnesia Impaired memory.

dysmorphophobia BODY DYSMORPHIC DISORDER.

dyspareunia Physical pain in sexual intercourse, usually emotionally caused and more commonly experienced by women; may also result from cystitis, urethritis, or other medical conditions. *See also* Genitopelvic pain/penetration disorder.

dysphagia Difficulty in swallowing.

dysphasia Difficulty in comprehending oral language (receptive dysphasia) or in trying to express verbal language (expressive dysphasia).

dysphonia Difficulty or pain in speaking.

dysphoria Feeling of unpleasantness or discomfort; a mood of general dissatisfaction, restlessness, depression, and anxiety.

dysphoric mood *See* dysphoria.

dysprosody Loss of normal speech melody (prosody).

dyssocial behavior Former term for antisocial behavior.

dyssomnias Disturbances in the amount, quality, or timing of sleep. *See* insomnia disorder, hypersomnia disorder, and circadian rhythm disorder. *Compare* parasomnias.

dysthymia Mood disorder characterized by chronic depressed mood for at least 2 years that is not severe enough to meet criteria for major depressive episode. Also called depressive neurosis. *See also* depression.

dystonia Extrapyramidal motor disturbance consisting of slow, sustained contractions of the axial or appendicular musculature; one movement often predominates, leading to relatively sustained postural deviations; acute dystonic reactions (facial grimacing, torticollis) are occasionally seen with the initiation of antipsychotic drug therapy.

E

early ejaculation DSM-5 term for premature ejaculation.

eating disorders Disorders characterized by a marked disturbance in eating behavior; they include anorexia nervosa, bulimia nervosa, pica, and rumination disorder of infancy.

echolalia Repetition of another person's words or phrases, as observed in certain cases of schizophrenia, particularly the catatonic types. The behavior is considered by some authors to be an attempt by the patient to maintain a continuity of thought processes.

echopraxia Repetition of another person's movements, as observed in some cases of catatonic schizophrenia.

ecology Study of the mutual relationships between living things and their environment; includes such studies as the differential incidence of mental disorders in various populations and the distribution of crime and delinquency within a specified geographical area.

ecopsychiatry Study of genetic data and hypotheses about the role of social factors in mental disease.

ecstasy **1.** State of rapturous delight. **2.** Slang term for methylenedioxymethamphetamine (MDMA).

ECT Electroconvulsive therapy.

ectomorphic Thin, characterized by a linear body musculature; one of Sheldon's constitutional types. *Compare* endomorphic; mesomorphic.

educable Capable of achieving a fourth- or fifth-grade academic level; describes the mildly mentally retarded (LQ of 50–55 to 70). *Compare* trainable.

educational psychology Area of psychology concerned with the application of psychological theories to teaching.

EEG Electroencephalogram.

ego One of the three components of the psychic apparatus in the Freudian structural framework, the others being the id and the superego. It occupies a position between the primal instincts and the demands of the outer world, therefore mediating between the person and external reality. In so doing, it performs the important functions of perceiving the needs of the self, both physical and psychological, the qualities and attitudes of the environment. It evaluates, coordinates, and integrates those perceptions so that internal demands can be adjusted to external requirements. It is also responsible for certain defensive functions to protect the person against the demands of the id and the superego. Although the ego has some conscious components, many of its operations are automatic; adaptation to reality is perhaps its most important function.

ego-alien Denoting aspects of a person's personality that are viewed as repugnant, unacceptable, or inconsistent with the rest of the personality. Also called ego-dystonic. *Compare* ego-syntonic.

ego analysis Psychoanalytic study of the manner in which the ego operates, especially in relation to intrapsychic conflicts. *See also* ego psychology.

ego boundaries Concept introduced by Paul Federn that refers to the ability of the intact ego to differentiate the real from the unreal. Ego boundaries prevent repressed unconscious material from overwhelming the ego; when that happens, a person experiences depersonalization and derealization. Boundaries are said to be weakened in schizophrenia and dissociative states.

egocentric Self-centered; selfishly preoccupied with one's own needs; lacking interest in others.

ego-coping skill Adaptive method or capacity developed by a person to deal with or overcome a psychological or social problem.

ego defense Defense mechanism to protect the person against the demands of the id and the superego.

ego-dystonic EGO-ALIEN.

ego-dystonic homosexuality Controversial term for the purported state of a person who has unwanted and distressful homosexual arousal and wishes to acquire or increase heterosexual arousal. Removed from DSM for the DSM-III-R revision of the book.

ego ideal Part of the personality representing a fusion of the ego and the superego; feelings of self-satisfaction are experienced when the person's thoughts, behavior, or impulses coincide with an internalized goal or ideal.

egomania Morbid self-preoccupation or self-centeredness. *See also* narcissism.

ego model Person after whom one patterns the ego.

ego psychology Study of the operations of ego in regard to control and regulation of instinctual drives, the relation to reality, and the development of object relations. *See also* ego analysis.

ego strength Degree to which the ego's functions, for example, perception, thinking, and speaking, are maintained.

ego-syntonic Denoting aspects of a person's personality that are viewed as acceptable and consistent with their total personality. *Compare* ego-alien.

eidetic image Unusually vivid or exact mental image seen or imagined event; may include color or movement.

ejaculation Expulsion of semen and seminal fluid from the urethra, as in male orgasm.

ejaculatory incompetence INHIBITED MALE ORGASM.

elaboration Unconscious process of embellishing the symbolic content of a dream.

elation Affect consisting of feelings of joy, euphoria, triumph, intense self-satisfaction, or optimism.

elective mutism Childhood mental disorder in which a child who is able and willing to speak to selected persons persistently refuses to speak in other social or school situations.

Electra complex Obsolete and controversial term for a supposed female analog of the Oedipus complex in the male; infrequently used term to describe unresolved developmental conflicts influencing a woman's relationships with men.

electroconvulsive therapy (ECT) Convulsive therapy, usually for depression, that involves the application of electric current to the brain for a fraction of a second through scalp electrodes to induce a convulsive reaction and unconsciousness.

electroencephalogram (EEG) Recording of the brain's electrical potentials obtained by scalp electrodes.

electromyogram (EMG) Recording of the electrical activity of muscles at specific sites.

electroshock therapy (EST) *See* electroconvulsive therapy.

electrostimulation In aversion therapy, a negative conditioning technique consisting of (usually painful) electric shocks.

elevated mood Air of confidence and enjoyment; a mood more cheerful than normal but not necessarily pathologic.

elimination disorders Inability as a result of physiologic or psychological immaturity to maintain bowel control (functional encopresis) or bladder control (functional enuresis).

elopement Escape; absenting oneself from a mental hospital without permission.

emancipated minor Legal term for a minor who exercises general control over their life and hence has the legal rights of an adult.

EMG Electromyogram.

emotion Complex feeling state with psychic, somatic, and behavioral components; external manifestation of emotion is affect.

emotional deprivation Relative lack of environmental or interpersonal experiences during the early developmental years. *See also* sensory deprivation.

emotional disorder Lay term for a mental illness or mental disorder; in common usage it does not specifically imply a mood disorder or schizophrenia.

emotional disturbance Emotional disorder or illness. *See also* mental disorder.

emotional illness General term for a behavioral or psychological syndrome or pattern associated with distress, disability, or increased risk of suffering.

emotional insight Deeper level of understanding or awareness that is more likely to lead to positive changes in personality and behavior.

emotional lability Excessive emotional responsiveness characterized by unstable and rapidly changing emotions.

emotional support Encouragement, hope, and inspiration given to one person by another.

empathy Intellectual and emotional awareness and understanding of another person's state of mind, involving the projection of oneself into another person's frame of reference; an important ability in a successful therapist or a helpful group member. *Compare* sympathy.

empty nest syndrome Depression that can occur in men and women when their youngest child is about to leave or has left home.

encapsulated delusion Delusion that has no significant effect on behavior.

encephalitis Inflammation of the brain.

encephalopathy Any disease of the brain.

encopresis Repeated passage of feces in inappropriate places, such as clothing or bed; diagnosis not made until after age 4.

encounter group Form of sensitivity training, introduced and developed by Jacob Moreno in 1914, that emphasizes the experiencing of individual relationships within the group and that minimizes intellectual and didactic input; the group focuses on the present, rather than concerning itself with the past or outside problems of its members. *See also* sensitivity training group.

endemic Belonging, native, restricted, or peculiar to a particular people, country, locality, or region.

endocrine disorder Dysfunction of any of the endocrine glands, frequently with psychiatric manifestations.

endogamy Marriage within a specific group. *Compare* exogamy.

endogenous depression Obsolete term for a type of depression that originates within the person and is not related to external events, with a cause that is biologic or somatic. Also called nonreactive depression.

endomorphic Obese, with prominence of the abdomen; one of Sheldon's constitutional types. *Compare* ectomorphic; mesomorphic.

endorphin Any of several endogenous opioid peptides (α-, β-, or γ-endorphin) found in highest concentrations in the pituitary gland and which has analgesic and behavioral effects in animals. *See also* enkephalin.

engram Memory trace, the neurophysiologic substrate of memory.

enkephalin Endogenous opioid peptide released by β-endorphin that has analgesic properties and many of the actions of morphine.

entomophobia Fear of insects.

enuresis Repeated incontinence of urine in inappropriate places, such as clothing or bed; diagnosis not made until after age 5.

epidemiology In psychiatry, the study of the incidence, prevalence, control, and distribution of mental disorders within a particular population.

epigenesas Term introduced by Erik Erikson to refer to the stages of ego and social development.

epilepsy Neurologic disorder resulting from a sudden, excessive, disorderly discharge of neurons in either a structurally normal or a diseased cerebral cortex; characterized by paroxysmal recurrence of short-lived disturbances of consciousness, involuntary convulsive muscle movements, psychic or sensory disturbances, or some combination thereof. Termed idiopathic epilepsy when there is no identifiable organic cause. For types of epilepsy, see the specific term.

epileptic dementia Epilepsy accompanied by progressive mental and intellectual impairment; some believe that the circulatory disturbances during epileptic attacks cause nerve cell degeneration and lead to dementia.

epileptic equivalent Epileptic phenomenon that is neither grand mal nor petit mal. *See also* complex partial seizure.

epileptic personality EXPLOSIVE PERSONALITY.

epinephrine Sympathomimetic catecholamine formed from norepinephrine and the major hormone secreted by the adrenal medulla; its release during states of fear or anxiety produces many of the physiologic changes associated with those emotions. Also called adrenaline.

episodic Denoting an illness in which there are sustained disturbances clearly distinguished from previous functioning.

epistemology Study or theory of the nature and grounds of knowledge, especially with reference to its limits and validity.

erectile dysfunction MALE ERECTILE DISORDER.

eremophobia Abnormal fear of being by oneself.

ergasia Adolf Meyer’s term for a person’s total activity, as opposed to the functioning of parts of the whole.

Erikson, Erik (1902–1990) Psychoanalyst noted for his theory of ego development and psychosocial development, which he conceptualized in terms of social adaptation as it relates to Sigmund Freud’s formulations.

erogenous zone Any area of the body, principally the genitals, anus, and mouth, capable of being stimulated sexually.

eros SEXUAL DRIVE.

erotic Invested with sexual feeling.

erotomania Delusional conviction that another person is in love with them; typically the object of the delusion is of higher rank or status. Also referred to as de Clérambault syndrome or psychose passionelle.

erythrophobia Abnormal fear of blushing.

escape learning *See* avoidance and escape learning.

ESP Extrasensory perception.

EST Electroshock therapy.

estrogen Hormone produced mainly by the ovaries and responsible for the development of the female reproductive organs and secondary sex characteristics: for example, estradiol, estriol, estrone. *Compare* androgen.

ethnocentrism Conviction that one's own group is superior to other groups; impairs one's ability to evaluate members of another group realistically or to communicate with them on an open, equal, and person-to-person basis.

ethnology Branch of anthropology dealing with the division of mankind into races and their origin, history, customs, and institutions.

ethology Study of animal behavior; often applied to the understanding of human behavior.

etiology Study of the causes of disease and their mode of operation.

euergasia Word used by Adolf Meyer to mean normal mental functioning.

euphoria Exaggerated feeling of well-being that is inappropriate to apparent events; may be induced by drugs such as opiates, amphetamines, and alcohol.

euphoric mood *See* euphoria.

euphorohallucinogen Substance capable of producing euphoric hallucinations.

euthymia Normal range of mood, implying absence of depressed or elevated mood.

euthymic Denoting a normal mood.

evasion Act of not facing up to or of strategically eluding something; consists of suppressing an idea that is next in a thought series and replacing it with another idea closely related to it. Also called paralogia; perverted logic.

event-related euphoria Morbid or abnormal sense of well-being associated with a specific situation or event.

evoked potential (EP) Following repetitive stimuli, the characteristic EEG waveform that remains after averaging out most of the brain electrical activity; clinically useful in evaluating the functional integrity of the somatosensory or special sensory pathways.

exaltation Feeling of intense elation and grandeur.

excited Agitated, purposeless motor activity uninfluenced by external stimuli.

excitement phase Stage in the human sexual response after sexual stimulation, as described by Masters and Johnson, characterized by an objective sense of pleasure and accompanying physical changes (penile erection and vaginal lubrication).

excitoxicity Increased simulation of neurons due to injury or chemical neurotransmitters that cause cell death.

excoriation disorder Disorder characterized by compulsive picking of one's own skin, resulting in lesions, despite repeated efforts to decrease or stop picking. Also called skin-picking disorder.

executive ego function Part of the ego that helps maintain or manage one's relationship to and sense of reality.

exhaustion state Final stage of the body's response to major stress, as in the general adaptation syndrome.

exhibitionism Paraphilia in which a man exposes his genitals to females in a socially inappropriate fashion; rarely occurs in women. Also called exhibitionistic disorder.

existentialism Philosophic theory that questions the purpose and nature of existence itself; a fundamental focus is on the meaning of life in face of death and the end of one's personal existence.

existential psychotherapy Type of therapy, based on existential philosophy, that puts the emphasis on here-and-now interaction and on feeling experiences, rather than on rational thinking; little attention is given to patient resistances, and the therapist is involved on the same level and to the same degree as the patient. *See also* phenomenology.

exogamy Marriage outside of a specific group; in a biologic sense, the union of gametes of unrelated parents. *Compare* endogamy.

exogenous In psychiatry, denoting disordered behavior produced by forces outside of the body, as in adjustment disorder.

exorcism Magical practice in which mystical incantations are invoked to remove demons that are alleged to have entered the mind.

expansive mood Expression of feelings without restraint, frequently with an overestimation of their significance or importance. Seen in mania and grandiose delusional disorder.

experiencing Feeling emotions and sensations, as opposed to thinking; being involved in what is happening, rather than standing back at a distance and theorizing.

experimental bias Error in construction of an experiment or study that favors one outcome over another.

experimental design Manner in which an experiment is logically organized in order to maximize the probability of obtaining real effects.

experimental group In an experimental design, the group that is exposed to the experimental manipulation under study. Compare control group.

experimental neurosis Abnormal behavior produced in a laboratory setting; used by Ivan Pavlov to describe symptoms of extreme and persistent agitation that he produced in dogs.

expert witness Legal concept that refers to the physician in the courtroom who is deemed sufficiently knowledgeable in a field to draw informed conclusions from data, for example, that a patient meets the required criteria for commitment or for an insanity defense.

explosive personality Personality type characterized by rigidity, egocentricity, selfishness, religiosity, seclusiveness, explosive outbursts of emotion, and extreme rage reactions when frustrated; enuresis is common.

expressive aphasia Disturbance of speech in which understanding remains, but ability to speak is grossly impaired; halting, laborious, and inaccurate speech. Also known as Broca's, nonfluent, and motor aphasias.

expressive dysphasia Difficulty in expressing verbal language; the ability to understand language is intact.

extended-family therapy Type of family therapy that involves family members, beyond the nuclear family, who are closely associated with it and affect it. *See also* social network therapy.

externalization More general term than projection that refers to the tendency to perceive in the external world and in external objects elements of one's own personality, including instinctual impulses, conflicts, moods, attitudes, and styles of thinking.

external validity Statistical term that refers to how well a test measures what it purports to measure and identifies what it is supposed to identify.

extinction Process by which an operant behavior occurs less frequently when its performance is no longer reinforced.

extrapsychic conflict Conflict that arises between a person and their environment. Also called interpersonal conflict. *Compare* intrapsychic conflict.

extrapyramidal dyskinesia Movement disorder related to dysfunction of the extrapyramidal motor system; signs include a variety of involuntary movements and postures, muscular rigidity, tremor, and gait disturbance, as seen in Parkinson disease, chorea, athetosis, and hemiballismus. Extrapyramidal dyskinetic syndromes may occur as a side effect of antipsychotic drugs; such drug-induced extrapyramidal effects include a parkinsonian syndrome, akathisia, acute dystonic reactions, and tardive dyskinesia.

extrapyramidal effect Bizarre, involuntary motor movement; a central nervous system side effect sometimes produced by antipsychotic drugs. *See also* extrapyramidal dyskinesia.

extrapyramidal motor system Polysynaptic neural pathways involving the basal ganglia and related subcortical nuclei that influence motor behavior.

extrapyramidal syndrome Abnormalities of movement related to injury of motor pathways other than the pyramidal tract; for example, parkinsonism, akathisia, dystonia, tardive dyskinesia.

extrasensory perception (ESP) Experiencing an external event by means other than the five senses, as by telepathy or clairvoyance.

extroversion, extraversion State of one's energies being directed outside oneself. *Compare* introversion.

F

factitious disorder Mental disorder characterized by the voluntary production of false or unreal physical or psychological symptoms; unlike malingering, there is no apparent goal or obvious benefit. Also called Munchausen syndrome. *Compare* somatic symptom disorder; somatoform disorders.

factitious disorder by proxy A disorder in which one person deceitfully creates false signs or symptoms of illness in another person who is under their care; most commonly this condition involves a mother presenting her child as ill. In some cases actual injury or illness may be inflicted on the dependent person. Diagnosed as "factitious disorder imposed on another" in DSM-5.

factitious disorder imposed on another *See* factitious disorder by proxy.

factor analysis Data reduction technique used to reduce a large number of variables to a smaller number of linear combinations of variables.

failure to thrive Delay in physical growth in infants and young children; often accompanied by impaired social and motor development; commonly associated with parental deprivation or neglect when no medical illness is detected. *See* reactive attachment disorder.

false memory A person's recollection and belief of an event that did not actually occur. In false memory syndrome, persons erroneously believe that they sustained an emotional or physical (e.g., sexual) trauma early in life.

false negative Diagnosis of a disorder as being absent in a person (tested negative) when in fact it is present.

false positive Diagnosis of a disorder as being present in a person (tested positive) when in fact it is not present.

falsifiable hypothesis Testable hypothesis that can be confirmed or disconfirmed.

family neurosis Mental disorder in which a person's psychopathology is unconsciously interrelated with that of other members of the family.

family therapy Treatment of more than one member of a family in the same session; family relationships and processes are explored as potential causes of mental disorder in one or more of the family members. *See also* extended-family therapy.

fantasy Daydream; fabricated mental picture of a situation or chain of events. A form of thinking dominated by unconscious material and primary processes that seeks wish fulfillment and immediate solutions to conflicts; may serve as the matrix for creativity or for neurotic distortions of reality.

fatal familial insomnia An inherited prion disease characterized by insomnia and autonomic nervous system dysfunction (e.g., fever, sweating, tachycardia).

father surrogate, father substitute In psychoanalysis, a person onto whom the patient projects their father image and to whom they respond unconsciously in an inappropriate and unrealistic manner, with the feelings and attitudes held toward the real father.

fatigue A feeling of weariness, sleepiness, or irritability after a period of mental or bodily activity. Seen in depression, anxiety, neurasthenia, and somatoform disorders.

fausse reconnaissance False recognition, a feature of paramnesia. Can occur in delusional disorders.

faux de mieux Literally, "for want of anything better," connoting in psychiatry a person choosing a homosexual relationship when no partner of the opposite sex is available.

FDA Food and Drug Administration.

fear Unpleasurable emotional state consisting of psychophysiologic changes in response to a realistic threat or danger. *Compare* anxiety.

feeble-mindedness Obsolete term for mental retardation, which is also called intellectual developmental disorder.

feedback 1. In a given system, the return, as input, of some form of information regarding the output; used as a regulatory mechanism. **2.** In psychiatry, the verbally or otherwise expressed response to a person's behavior by another person or a group.

feeding disorder of infancy or childhood *See* avoidant/restrictive food intake disorder.

fellatio Use of the mouth or tongue to stimulate the male genitalia.

femaleness Anatomic and physiologic features relating to female procreative functions.

female orgasmic disorder Disorder characterized by a woman's inability to achieve orgasm by coitus or masturbation.

feminine identity Inner sense of gender affiliation with females. *Compare* masculine identity.

Ferenczi, Sandor (1873–1933) Hungarian psychoanalyst who was one of Sigmund Freud's early followers and a brilliant contributor to all aspects of psychoanalysis; he came to favor more active and personal techniques than Freud's, to the point that his adherence to psychoanalysis during his last years was questioned.

fetal alcohol syndrome A syndrome that occurs when mothers consume alcohol during pregnancy resulting in fetuses born with birth defects, CNS dysfunction, and intellectual disability.

fetishism Paraphilia in which sexual excitement and gratification are achieved by substituting an inanimate object (such as a shoe, piece of underwear, or other article of clothing) for a human love object. Also called fetishistic disorder.

fibromyalgia A chronic pain disorder characterized by pain and stiffness of the soft tissues (e.g., muscles, ligaments, tendons).

field theory Conceptual approach to the study of personality formulated by Kurt Lewin that focuses on an operational analysis of the causal determinants of human behavior; it is expressed in geometric and mathematical terms borrowed from physics in an attempt to provide a framework suitable to the scientific study of human behavior. The person and their environment together constitute the life space, a complex field of forces acting on the personality and determining behavior.

finger agnosia Agnosia characterized by inability to name fingers; suggests a lesion in the dominant parietal lobe.

fixation 1. Arrest of psychosexual development at any stage before complete maturation. 2. Close and paralyzing attachment to another person, such as one's mother or father.

fixed-interval schedule *See* schedule of reinforcement.

fixed-ratio schedule *See* schedule of reinforcement.

flagellantism, flagellation Process by which sexual partners are aroused and gratified by whipping or being whipped.

flashback hallucinosis Spontaneous recurrence, after a drug-free period, of hallucinations similar to those experienced during an acute toxic episode; often associated with repeated ingestions of LSD. Hallucinations are predominantly visual and may last for months after the last use of a drug.

flat affect Absence or near absence of any signs of affective expression.

flexibilitas cerea CATALEPSY.

flight of ideas Rapid succession of fragmentary thoughts or speech in which content changes abruptly and speech may be incoherent, as seen in mania.

floccillation Aimless plucking or picking, usually at bed-clothes or clothing, commonly seen in senile psychosis and delirium.

flooding Behavior therapy designed to extinguish phobias or anxiety through the presentation of the aversive stimuli in intense forms until the emotional responses cease. Also called implosion therapy.

fluent aphasia Aphasia characterized by inability to understand the spoken word; fluent but incoherent speech is present. Also called Wernicke aphasia, sensory aphasia, and receptive aphasia.

folie à deux Mental illness shared by two persons, usually involving a common delusional system; if it involves three persons, it is referred to as folie à trios, and so forth. *See* shared psychotic disorder.

follow-up examination To the physician, the aftercare and monitoring of patients' responses to treatment and the state of their physical health or mental status.

Food and Drug Administration (FDA) Federal agency that standards for the sale and use of drugs, food substances, and cosmetics.

forensic psychiatry Branch of psychiatry concerned with the aspects of mental illness.

foreplay Sexual play that precedes sexual intercourse. Also called forepleasure.

forepleasure FOREPLAY.

formal operations Jean Piaget's label for completely developed logical thinking capacities. *See also* Piaget, Jean.

formal thought disorder Disturbance in the form of thought rather than the content of thought; thinking characterized by loosened associations, neologisms, and illogical constructs; thought process is disordered, and the person is defined as psychotic. Characteristic of schizophrenia.

formication Tactile hallucination involving the sensation that tiny insects are crawling over the skin; most commonly encountered in cocaine addiction and delirium tremens.

for-profit hospital Investor-owned or proprietary hospital; hospital owned and operated by physicians or corporations that earns a profit for its investors.

fragile X syndrome A syndrome resulting from a mutation on the X chromosome. Includes severe intellectual disability, a large head, long face, prominent ears, and, in males, large testicles.

fragmentary delusion Poorly elaborated delusion, often one of many with no apparent interconnection.

fraternal twins DIZYGOTIC TWINS.

free association Investigative psychoanalytic technique devised by Freud in which the patient seeks to verbalize without reservation or censorship the passing contents of their mind.

freebase Cocaine hydrochloride mixed with ammonia and an alkali solution, and then extracted with a solvent into a crystalline form. *See also* crack.

free-floating anxiety Severe, pervasive, generalized anxiety that is not attached to any particular idea, object, or event; observed particularly in anxiety disorders, although it may be seen in some cases of schizophrenia.

Fregoli syndrome The delusional belief that a known person is an imposter who assumes different appearances or disguises.

frequency Number of cases having a certain score or characteristic; relative frequency measures the number of persons in a specific group (e.g., sex or age) who have a disorder.

frequency distribution Statistical description of raw data in terms of the number of cases that fall into each interval within a set of data; often presented graphically in the form of a frequency histogram or frequency polygram.

Freud, Anna (1895–1982) Daughter of Sigmund Freud noted for her contributions to the developmental theory of psychoanalysis and the mechanisms of defense.

Freud, Sigmund (1856–1939) Austrian psychiatrist and the founder of psychoanalysis. With Josef Breuer, he explored the potentialities of cathartic therapy and then went on to develop the analytic technique and such fundamental concepts as mental sublimation, as well as superego, ego, and id formation and their applications throughout all spheres of human behavior. Among his publications are *The Interpretation of Dreams* (1899). *Studies on Hysteria* (1895, with Breuer), and *Three Essays on the Theory of Sexuality* (1905).

frigidity Outdated term referring, in the female, to lack of sexual response or feeling, ranging from complete lack of arousal to incomplete climax.

frontal lobe syndrome Mental disorder characterized by a marked change in personality, with development of certain relatively characteristic patterns of relating to the environment that have been associated with lesions of the frontal lobes; such patterns include emotional lability, impairment in impulse control and social judgment, and marked apathy and indifference.

frontotemporal dementia Rare form of presenile dementia caused by cerebral atrophy predominantly in the frontotemporal regions of the brain; early stages are characterized by personality and behavior changes. The following progressive cognitive deterioration is indistinguishable clinically from the far more common Alzheimer disease, in which the cerebral atrophy is diffuse. Also called Pick disease. *See also* dementia of the Alzheimer type.

frottage, frotteurism Sexual aberration in which arousal results from rubbing up against someone, usually without specific genital contact, as in a crowd; a person so afflicted is a frotteur. Also called frotteuristic disorder.

frustration Result of the thwarting of any goal-directed behavior; the ability to tolerate frustration and delay gratification is considered a sign of maturity and good ego strength.

fugue Called dissociative fugue in DSM-5, a subtype of dissociative amnesia characterized by a period of almost complete amnesia, during which a person actually flees from an immediate life situation and begins a different life pattern; apart from the amnesia, mental faculties and skills are usually unimpaired. *See also* psychogenic amnesia.

fulfillment Satisfaction of a need or wish.

functional Denoting changes in functioning not attributable to known organic alterations.

functional disorder Disorder that is not caused by an anatomical defect or any other identifiable or demonstrable cause. *Compare* organic disorder.

functional neurologic disorder *See* conversion disorder.

functional neurologic symptom disorder Mental disorder in which the patient experiences an involuntary limitation or alteration of physical function that is an expression of a psychological conflict or need, not of a physical disorder. Previously called conversion disorder in DSM-IV. *See also* hysteria.

functional speech disorder DEVELOPMENTAL ARTICULATION DISORDER.

fusion In psychoanalysis, the joining together of instincts which enables the person to function normally.

G

GABA γ-(gamma) aminobutyric acid.

GAF Scale GLOBAL ASSESSMENT OF FUNCTIONING SCALE.

galactorrhea Abnormal discharge of milk from the breast; may be a result of the endocrine influence of phenothiazine drugs.

galvanic skin response (GSR) Measurable change in the electrical resistance of the skin, used as an index of emotional response.

gambling disorder DSM-5 disorder characterized by persistent and recurrent maladaptive gambling that leads to economic problems and disturbances in personal, social, and occupational functioning. Also called pathologic gambling.

γ**-(gamma) aminobutyric acid (GABA)** Inhibitory amino acid neurotransmitter synthesized by the actions of glutamic acid decarboxylase; GABA receptors are located at postsynaptic sites.

gamophobia Abnormal fear of marriage.

Ganser syndrome Rare atypical disorder, seen in prisoners, characterized by a giving of approximate answers to questions and of talking past the point; to be distinguished from factitious disorder and malingering.

gargoylism Old name for the gargoyle-like facies and dwarfism seen in Hunter and Hurler syndromes: metabolic disorders of mucopolysaccharide metabolism characterized by severe developmental skeletal deformities and mental retardation.

GAS General adaptation syndrome.

gatekeeper In community psychiatry, a person who evaluates the degree of psychological or environmental stress sufficient to enable a patient to gain access to the mental health care system.

gateway drugs Substances of abuse, such as alcohol and marijuana, which provide major portals of entry into abuse of other drugs; considered particularly dangerous because they are believed by so many to be relatively harmless.

Gault decision U.S. Supreme Court 1967 decision mandating fair and accurate fact-finding procedures for juveniles when serious punishment could be inflicted should they be found guilty; rights guaranteed the juvenile include the right to notification of the specific charges, the right to counsel, the right against self-incrimination, and the right to confront and cross-examine the accusers.

gay 1. Preferred term for a homosexual, especially male. **2.** Denoting a homosexual or the lifestyle thereof.

gegenhalten Neurologic term (from the German) for involuntary active resistance to passive movement of the extremities, as may occur in cerebral cortical disorders.

gender dysphoria The DSM-5 term for gender identity disorder. May first appear in childhood, adolescence, or adulthood.

gender identity Culturally determined sets of attitudes, behavior patterns, and physical attributes usually associated with masculinity and femininity. *Compare* sexual identity.

gender identity disorder Psychosexual disorder in which a person feels discomfort with and inappropriateness of their biologic sex, with a marked preference for the clothing and activities of the opposite sex and/or repudiation of the sex organs. Also called gender dysphoria. *See also* transsexualism.

gender role Public declaration of gender; the image of maleness or femaleness that is communicated to others which may or may not coincide with gender identity.

general adaptation syndrome (GAS) Hans Selye's term for the responses of the body to major stress, passing through the alarm reaction, resistance and, finally, exhaustion.

generalization Process by which a behavior occurs in a setting in which it had not previously been reinforced.

generalized anxiety *See* free-floating anxiety.

generalized anxiety disorder An anxiety disorder characterized by chronic generalized anxiety consisting of feelings of tension, tremor, apprehension, and hyperarousal not attached to any particular idea, object, or event. *See* free-floating anxiety.

generalized tonic–clonic seizure Generalized onset of tonic–clonic movements of the limbs, tongue biting, and incontinence followed by slow, gradual recovery of consciousness and cognition. Also called grand mal seizure.

general paralysis, general paresis Mental disorder caused by chronic (tertiary) neurosyphilis.

general systems theory Theoretical framework asserting that the universe is composed of interacting components that are interrelated; in psychiatry, it emphasizes an integrated, holistic approach to understanding behavior.

genetic counseling Presentation and discussion, generally with a prospective parental couple, of factors involved in the inheritance of pathologic conditions as they relate to the couple's generic endowment.

genetic endowment Characteristics that are inherited, usually regarding potential capacities of intelligence, temperament, and general adaptability.

genetic marker Detectable sign of the presence of or vulnerability to inherited disease, such as a measurable biochemical abnormality or an identifiable defect in a particular gene.

genetic material In psychiatry and psychoanalysis, a term used to reflect the data from a patient's personal past history that are useful in developing an understanding of the psychodynamics of their present adaptation.

genital phase Final stage of psychosexual development, occurring during puberty, in which sexual gratification is achieved from genital-to-genital contact and the capacity exists for a mature, affectionate relationship with someone of the opposite sex.

genotype Genetic endowment of a person, consisting of a set of genes received from each parent at the time of conception. *Compare* phenotype.

geriatric psychiatry Branch of psychiatry concerned with the mental disorders that accompany old age. Also called geropsychiatry.

geriatrics Branch of medicine concerned with the aged and the problems of aging. *See also* gerontology.

genito–pelvic pain/penetration disorder Diagnostic category in DSM-5 referring to one or more of the following: genito–pelvic pain; difficulty having intercourse; fear of pain or penetration; and tension of the pelvic floor muscles; previously divided into the distinct categories of dyspareunia and vaginismus.

gerontology Scientific study of aging.

gerontophilia Sexual attraction for the old and the aged by a young person.

gerontophobia Fear of the older adults or of the aging process.

geropsychiatry GERIATRIC PSYCHIATRY.

Gerstmann–Straussler–Scheinker disease DEVELOPMENTAL ARITHMETIC DISORDER.

Gesell Developmental Schedules Developmental landmarks in infants and children that cover ages 8 weeks to 3.5 years. Data are obtained by direct observation of the child's responses to standard toys and other controlled stimulus objects and are supplemented by developmental information provided by the mother or primary caretaker; the schedules yield scores indicating the child's level of development in four separate areas: motor, adaptive, language, and personal and social.

gestalt psychology School of psychology primarily concerned with perceptual processes; a major tenet is that the whole is greater than the sum of its parts. Its development is associated particularly with Max Wertheimer, Wolfgang Koehler, and Kurt Koffka.

gestalt therapy Psychotherapy developed by Frederick S. Perls that emphasizes the treatment of the person as a whole: one's biologic component parts and their organic functioning, one's perceptual configuration, and one's interrelationships with the outside world. It can be used in either an individual or a group therapy setting; focuses on the sensory awareness of the person's here-and-now experiences, rather than on past recollections or future expectations; and uses role playing and other techniques to promote the patient's growth process and development to full potential.

Gilles de la Tourette syndrome *See* Tourette disorder.

global aphasia Combination of grossly nonfluent aphasia and severe fluent aphasia.

Global Assessment of Functioning Scale (GAF Scale) Scale used in DSM to describe the highest social, occupational, or educational level of functioning of a person in the 12 months preceding the current evaluation.

global developmental delay Preferred term for a condition of intellectual and adaptive impairment in children that fail to meet expected developmental milestones in multiple areas of intellectual functioning before 5 years of age. *See also* intellectual disability.

globus hystericus Hysterical symptom in which a person is disturbed by the sensation of a lump in the throat.

glossolalia Unintelligible jargon that has meaning to the speaker but not to the listener. Occurs in schizophrenia.

go-around Technique used in group therapy in which the therapist requires each member of the group to respond to another member, a theme, or an association to encourage the participation of all members in the group.

gonadal dysgenesis TURNER SYNDROME.

grandiose delusion DELUSION OF GRANDEUR. *See* delusion.

grandiosity Exaggerated feeling of one's importance, power, knowledge, or identity. Occurs in delusional disorder and manic states. *See also* delusion of grandeur.

grand mal epilepsy Major form of epilepsy in which gross tonic–clonic convulsive seizures are accompanied by loss of consciousness and, often, incontinence of stool or urine; frequently preceded by an aura.

gray-out syndrome Psychosis that occurs in pilots flying at high altitudes, out of sight of the horizon.

grief Alteration in mood and affect consisting of sadness appropriate to a real loss; normally, it is self-limited. *See also* depression; mourning.

group *See* therapeutic group.

group analytic psychotherapy Term applied by S. H. Foulkes to his pioneering group therapy procedure in which interventions dealt primarily with group, rather than individual, forces and processes, and the group was used as the principal therapeutic agent.

group cohesion Mutual bonds formed between members of a group as a result of their concerted effort for a common interest and purpose; until cohesiveness is achieved, the group cannot concentrate its full energy on a common task.

group dynamics Phenomena that occur in groups from their inception to their termination. Interactions and interrelations among members and between the members and the therapist create tension, which maintains a constantly changing group equilibrium; interactions and the tension created are highly influenced by individual members' psychological makeup, unconscious instinctual drives, motives, wishes, and fantasies. Understanding and effectively using group dynamics are essential in group treatment. Also called group process.

group mind Autonomous and unified mental life in an assemblage of people bound together by mutual interests; a concept used by group therapists who focus on the group as a unit rather than on the individual members.

group practice Delivery of medical services by three or more physicians formally organized to provide care, consultation, diagnosis, and treatment; they share the use of equipment and personnel, and income from the medical practice is distributed among the members of the group.

group pressure Demand by group members that individual members submit and conform to group standards, values, and behavior.

group process GROUP DYNAMICS.

group psychotherapy Application of psychotherapeutic techniques to a group of patients, using interpatient interactions to effect changes in the maladaptive behavior of the individual members.

group relations theory *See* Allport's group relations theory.

GSR Galvanic skin response.

guardianship Person appointed by the courts for the care and management of a person or the property of another, as of a minor or a person incapable of managing their affairs.

guilt Emotional state associated with self-reproach and the need for punishment. In psychoanalysis, refers to a neurotic feeling of culpability that stems from a conflict between the ego and the superego that begins developmentally with parental disapproval and becomes internalized as conscience in the course of superego formation. Guilt has normal psychological and social functions, but special intensity or absence of guilt characterizes many mental disorders, such as depression and antisocial personality disorder, respectively. Some psychiatrists distinguish shame as a less internalized form of guilt that relates more to others than to the self. *See also* shame.

gustatory hallucination Hallucination primarily involving taste.

gynecomastia Female-like development of the male breasts; may occur as an adverse effect of antipsychotic and antidepressant drugs due to increased prolactin levels or anabolic–androgenic steroid abuse.

gynephobia Abnormal fear of women.

gyrectomy Psychosurgery involving excision of a cerebral gyrus.

H

habeas corpus Legal term for the right to petition a court to decide whether confinement has been undertaken with due process of law.

habit Behavior pattern acquired by frequent repetition that leads to regularity or increased facility of performance.

habituation 1. Simple form of learning in which the response to a repeated stimulus lessens over time. **2.** Psychological dependence on the continued use of a drug or chemical substance to maintain a sense of well-being, which can result in addiction.

halfway house Facility for mental patients who no longer need the full facilities of a hospital but are not yet ready to return to their communities.

hallucination False sensory perception occurring in the absence of any relevant external stimulation of the sensory modality involved. For types of hallucination, see the specific term.

hallucinogenic drug, hallucinogen Chemical agent that produces hallucinations, such as LSD and mescaline. *See also* euphorohallucinogen; psychotomimetic drug.

hallucinosis State in which a person experiences hallucinations without any impairment of consciousness.

haloperidol Butyrophenone antipsychotic drug (trade name, Haldol).

Halstead–Reitan Scale Battery of neuropsychological tests used to determine the location and effects of specific brain lesions. A great variety of functions are tested: concept function, abstraction, and visual acuity; dexterity; spatial memory; auditory perception, attention, and concentration; finger-oscillation; speech-sounds perceptions; visual perception; time sense; and sensory stimulation, stereognosis, and tactile perception.

Hamilton Depression Scale Scale of depression based upon a clinical interview with the patient in which the examiner asks about guilt, suicide, sleep habits, weight change, and other symptoms of depression.

haphephobia Abnormal fear of being touched.

haplology Rapid speech in which syllables are omitted; seen in certain manias and in schizophrenic conditions.

haptic hallucination Hallucination of touch.

harm avoidance A term used to describe a character trait in which the person avoids novel situations and taking risks; may be an inborn and genetically determined.

hashish Dried resinous tops of the marijuana plant (*Cannabis sativa*): the active ingredient is tetrahydrocannabinol, which is a potent psychedelic drug.

Health and Human Services Federal organization composed of the following: Office of Human Development Services, Public Health Service (includes Centers for Disease Control; Food and Drug Administration; Health Resources and Services Administration; National Institutes of Health; Alcohol, Drug Abuse, and Mental Health Administration; Agency for Toxic Substances and Disease Registry; and Indian Health Service), Social Security Administration, Health Care Financing Administration, and Family Support Administration. Formerly called Department of Health, Education, and Welfare (HEW).

health insurance Insurance that reimburses one for the costs of medical care or lost income arising from medical disability; may include coverage for the care of mental conditions.

health maintenance organization (HMO) Form of group practice by physicians, often including psychiatrists, and allied health professionals to provide comprehensive health services to subscribers who pay a fixed premium.

Health Systems Agency (HSA) Nonprofit, federally mandated, statewide organizations that promote or limit the development of health services and faculties depending on the needs of the particular state or locale. HSAs develop long- and short-term goals and plans, approve health care proposals requesting federal funding, review existing facilities and services, and suggest future consideration and renovation projects based on their findings.

healthy identification Modeling of oneself, consciously or unconsciously, on another person who has a sound psychic makeup; such identification has constructive results. *See also* imitation.

hearsay Out-of-court statement offered to prove the truth of the matter asserted; usually inadmissible as testimony.

hebephrenia Complex of symptoms, considered a form of schizophrenia, characterized by wild or silly behavior or mannerisms, inappropriate affect, frequent hypochondriacal complaints, and delusions and hallucinations that are transient and unsystematized. *See also* schizophrenia.

hedonism Pleasure-seeking behavior. *Compare* anhedonia.

helplessness **1.** Learned: State of apathy that occurs as a type of experimental neurosis in animals who cannot escape an aversive stimulus; proposed as the animal model of human depression in which a patient feels helpless to control events. **2.** Psychic: State that occasions the first expressions of anxiety in humans, for example, the experience of birth.

hematophobia Abnormal fear of the sight of blood.

herd instinct Desire to belong to a group and to participate in social activities; used by Wilfred Trotter to indicate the presence of a hypothetical social instinct in humans. In psychoanalysis, herd instinct is viewed as a social phenomenon, rather than as an instinct.

hermaphrodite Person who has both female and male gonadal tissue, usually with one sex dominating.

heroin Diacetylmorphine; an illicit, addictive alkaloid opioid that requires subsequent larger and larger amounts to achieve the same narcotic and analgesic effects. Injected intravenously, it produces a more rapid onset of euphoria than does morphine.

heterogeneity Dissimilarity in the genotypal structure of individuals originating through sexual reproduction.

heterosexuality Sexual attraction or contact between opposite-sex persons. The capacity for heterosexual arousal is probably innate, biologically programmed, and triggered in very early life, perhaps in part by olfactory modalities as seen in lower animals. *Compare* bisexuality; homosexuality.

heterozygous Possessing different allelic forms of a gene at a given locus in homologous chromosomes.

heuristic 1. Involving or serving as an aid to learning, discovery, or problem-solving by experimental and especially trial-and-error methods. **2.** Of or relating to exploratory problem-solving techniques that utilize self-educating techniques.

5-HIAA 5-Hydroxyindoleacetic acid.

histrionic personality disorder Condition in which the patient, usually an immature and dependent person, exhibits unstable, overreactive, and excitable self-dramatizing behavior that is aimed at gaining attention and is at times seductive, although the person may not be aware of that aim.

HIV Human immunodeficiency virus.

HMO Health maintenance organization.

hoarding disorder Disorder characterized by persistent difficulty parting with or discarding possessions; delusional beliefs about the accumulated items may be present. Part of obsessive-compulsive disorder in DSM-5.

holism In psychiatry, the study of the total person as a distinctive entity, rather than as a collection of various characteristics.

holophrastic Using a single word to express a combination of ideas; schizophrenic persons may use holophrastic language.

homeless Persons who have no permanent place of residence, often sleeping in the street, many of whom require psychiatric treatment or hospitalization.

homeostasis Tendency to maintain a constancy and stability of bodily processes to ensure optimal functioning; the state of bodily equilibrium and the processes whereby such equilibrium is maintained.

homophobia Fear of homosexual persons.

homosexuality Sexual attraction or contact between same-sex persons. Some authors distinguish two types: overt and latent. *Compare* bisexuality; heterosexuality. When referring to people, homosexual is considered derogatory and the preferred terms are gay and lesbian.

homosexual panic Sudden, acute onset of severe anxiety precipitated by the unconscious fear or conflict that one may be a homosexual or act out homosexual impulses.

homovanillic acid (HVA) Phenol found in human urine; as the major metabolite of dopamine, it is most often measured in psychiatric research.

Horney, Karen (1885–1952) Psychiatrist and psychoanalyst whose theories of the genesis of neurosis emphasized environmental and cultural factors and thus departed from the biologic-instinctual framework of orthodox freudian thought.

hostile transference *See* transference.

hostility Conflict, opposition, or resistance in thought or principle.

hotline Telephone assistance service for crisis intervention.

HSA Health Systems Agency.

5-HT 5-Hydroxytryptamine.

human immunodeficiency virus (HIV) An infection caused by a retrovirus that incorporates itself into deoxyribonucleic acid (DNA). Symptoms include fever, myalgia, headache, fatigue, gastrointestinal symptoms, and rash. Can cause acquired immunodeficiency syndrome (AIDS).

humanistic theory Group of diverse theories that share a holistic conceptualization that emphasizes the uniqueness, value, dignity, and worth of each human being as an individual. Human behavior is considered understandable only in terms of the meaning of experiences for the individual person; it represents a complex interplay of numerous physical, psychological, and sociocultural factors.

humiliation Sense of disgrace, dishonor, and shame; often experienced by depressed patients.

humor Defense mechanism that allows the overt expression of feelings and thoughts without personal discomfort or immobilization and does not produce an unpleasant effect on others; allows the individual to tolerate and yet focus on what is too terrible to be borne. Differs from wit, a form of displacement that involves distraction from the affective issue.

Huntington disease (chorea) Hereditary and progressive central nervous system disease characterized by jerking motions and progressive mental deterioration: inherited as an autosomal dominant, with onset in adult life.

HVA Homovanillic acid.

hydrocephalus Excessive accumulation of cerebrospinal fluid which dilates the cerebral ventricles.

hydrophobia In psychiatry and psychology, an abnormal fear of water.

hydrotherapy Use of water by external application in the treatment of disease.

5-hydroxyindoleacetic acid (5-HIAA) Metabolite of serotonin, the concentration of which can be measured in cerebrospinal fluid and serum: determination of 5-HIAA concentrations is used in psychiatric research and may help guide clinical practice.

5-hydroxytryptamine (5-HT) SEROTONIN.

hyperactivity Increased muscular activity. The term is commonly used to describe a disturbance found in children that is manifested by constant restlessness, overactivity, distractibility, and difficulties in learning. Also called hyperkinesis. *See also* attention-deficit hyperactivity disorder; minimal brain dysfunction.

hyperalgesia Excessive sensitivity to pain. Seen in somatoform disorder.

hyperarousal A state of increased psychological and physiologic tension marked by such effects as reduced pain tolerance, anxiety, exaggeration of startle responses, insomnia, fatigue, and accentuation of personality traits.

hyperesthesia Increased sensitivity to tactile stimulation.

hyperkinesis HYPERACTIVITY.

hyperkinetic syndrome Disorder characterized by excessive muscular activity (hyperactivity) such as restlessness, aggressiveness, and destructive activity. *See also* attention-deficit hyperactivity disorder; minimal brain dysfunction.

hypermnesia Exaggerated degree of retention and recall. It can be elicited by hypnosis and may be seen in certain prodigies; also may be a feature of obsessive-compulsive disorder (OCD), some cases of schizophrenia, and manic episodes of bipolar I disorder.

hyperorexia Extreme appetite. *See also* bulimia nervosa.

hyperphagia Increase in appetite and intake of food.

hyperpragia Excessive thinking and mental activity, generally associated with the manic phase of bipolar I disorder.

hypersexuality Term used to describe excessive or compulsive interest in sex that may result in sex addiction.

hypersomnia Disorder characterized by excessive time spent asleep which may be nonorganic, organic, narcoleptic, idiopathic, part of Klein–Levin syndrome, or primary in nature. Also called hypersomnolence disorder.

hypersomnolence disorder *See* hypersomnia.

hypertensive crisis HYPERTENSIVE ENCEPHALOPATHY.

hypertensive encephalopathy Acute syndrome in which severe hypertension is associated with headache, nausea, vomiting, visual disturbances, convulsions, and alterations in consciousness characterized by confusion, somnolence, stupor, and coma. Prompt lowering of the blood pressure by pharmacologic means may reverse the picture in 24 to 48 hours; if the blood pressure is not controlled, intracerebral hemorrhage and a fatal outcome may result. Usually, the patient has entered the malignant phase of essential or secondary hypertension, with marked blood pressure elevation (generally in the range of 250/150 mm Hg) and evidence of cardiac decompensation, declining renal function, and advanced hypertensive retinopathy; also seen as a side effect of monoamine oxidase inhibitors when tyramine-containing foods are consumed. Also called hypertensive crisis.

hyperthyroidism Excessive activity of the thyroid gland; may be associated with dementia, anxiety disorders, and insomnia. *Compare* hypothyroidism.

hyperventilation Excessive breathing, generally associated with anxiety, which can cause a reduction in blood carbon dioxide that produces symptoms of lightheadedness, palpitations, numbness and tingling periorally and in the extremities, and occasionally syncope.

hypervigilance Excessive attention to and focus on all internal and external stimuli; usually seen in delusional or paranoid states.

hypesthesia Diminished sensitivity to tactile stimulation.

hypnagogic hallucination Hallucination occurring while falling asleep, not ordinarily considered pathologic.

hypnoanalysis Use of hypnosis in psychoanalysis to gain access to unconscious processes that the patient cannot reveal by means of ordinary therapeutic maneuvers.

hypnodrama Psychodrama under hypnotic trance; the patient is put into a hypnotic trance and encouraged to act out various past experiences.

hypnoid state Freud’s term describing an alteration of consciousness that occurs characteristically in hysteria during periods of emotional stress: characterized by heightened suggestibility and provides a basis for hysterical somatic symptom formation.

hypnophobia Abnormal fear of sleep.

hypnopompic hallucination Hallucination occurring while awakening from sleep, ordinarily not considered pathologic.

hypnosis Artificially induced alteration of consciousness characterized by increased suggestibility and receptivity to direction.

hypnotherapy Therapy that makes use of hypnosis.

hypnotic Drug used for the express purpose of producing sleep. *Compare* sedative.

hypoactive sexual desire disorder Sexual desire disorder characterized by deficiency or absence of sexual fantasies and desire for sexual activity. Also called sexual interest/arousal disorder in women.

hypoactivity Decreased motor and cognitive activity, as in psychomotor retardation; visible slowing of thought, speech, and movements. Also called hypokinesis.

hypochondria Exaggerated concern about health that is based not on real medical pathology, but on unrealistic interpretations of physical signs or sensations as abnormal.

hypochondriacal neurosis HYPOCHONDRIASIS.

hypochondriasis *See* somatic symptom disorder.

hypoglycemia Abnormally small concentration of glucose in the circulating blood; associated with anxiety and depression.

hypomania Mood abnormality with the qualitative characteristics of mania, but less intense; characterizes the hypomanic episode of bipolar II disorder when lasting 4 to 7 days.

hypothalamus Principal center in the forebrain for integration of visceral functions involving the autonomic nervous system. Functions include regulation of sexual activity, water, fat, carbohydrate metabolism, and temperature; also appears to play a role in the nervous mechanisms underlying moods and motivational states.

hypothyroidism Decreased activity of the thyroid gland; may be associated with dementia, depression, and sleep disorders. *Compare* hyperthyroidism.

hysteria A term previously used for a group of conditions involving a sudden impairment of function in response to emotional stress.

hysterical anesthesia Functional disorder characterized by the absence of tactile sensation in an area of the body; observed in certain cases of conversion disorder.

hysterical personality *See* histrionic personality disorder.

hysterics Expression of emotion often accompanied by crying, laughing, and screaming; a term generally used by laypersons rather than by psychiatrists.

I

iatrogenic Denoting an unfavorable response to a mode of treatment induced by the treatment itself. *Compare* idiopathic.

ICD *International Classification of Diseases.*

ice Pure form of methamphetamine that can be either inhaled or injected intravenously by abusers; its psychological effects last for hours and are particularly potent. Unlike the crack cocaine, which has to be imported, ice is a synthetic drug that can be manufactured in domestic illicit laboratories.

ICT Insulin coma therapy.

Id One of the three components of the psychic apparatus in the Freudian structural framework, the others being the ego and superego. It operates unconsciously; harbors the innate, biologic, instinctual drives; is the source of psychic energy (libido); follows the pleasure principle; seeks immediate reduction of drive tension without regard for external reality; and is under the influence of the primary-process mental activity that characterizes the unconscious.

idealization Mental mechanism whereby a person consciously or unconsciously overestimates an admired attribute or aspect of another person.

idea of reference Misinterpretation of incidents and events in the outside world as having a direct personal reference to oneself; occasionally observed in normal persons, but frequently seen in paranoid patients. If present with sufficient frequency or intensity or if organized and systematized, they constitute delusions of reference.

ideas of unreality Thought that events are artificial, illusory, unpredictable, or do not exist.

ideational shield Intellectual, rational defense against the anxiety that persons would feel if they became vulnerable to the criticisms and rejection of others; as a result of their fear of being rejected, they may feel threatened if they criticize another person, an act that is unacceptable to them. In both group and individual therapy, conditions are set up that allow the participants to lower the ideational shield.

idée fixe Fixed idea that is recurrent and most often associated with obsessional states.

identical twins MONOZYGOTIC TWINS.

identification Unconscious defense mechanism by which a person patterns themself after another person; in the process, the self is more or less permanently altered. *See also* healthy identification; imitation.

identification with the aggressor Unconscious process by which a person incorporates within themself the mental image of a person who represents a source of frustration from the outside world; a primitive defense that operates in the interest and service of the developing ego. A classic example of this defense occurs toward the end of the oedipal stage, when a boy, whose main source of love and gratification is his mother, identifies with his father who represents the source of frustration, being the powerful rival for the mother; the child cannot master or run away from his father, so he is obliged to identify with him.

identity One's global role in life and the perception of the sense of self; problems with identity are common during adolescence, in schizophrenia, and in the borderline and schizotypal personalities.

identity crisis Social role conflict as perceived by a person; loss of the sense of personal sameness and historical continuity, and/or inability to accept or adopt the role the person believes is expected by society. Identity crises are frequent in adolescence.

identity disorder A disorder characterized by a chaotic sense of self; a loss of the sense of personal sameness, usually involving a social role conflict as perceived by the individual. It is common in adolescence, when adolescents feel unwilling or unable to accept or adopt the roles they believe are expected of them by society; often manifested by isolation, withdrawal, rebelliousness, negativity, and extremism. Not a DSM-5 diagnosis.

idiopathic Without known or identifiable cause. *Compare* iatrogenic.

idiot Obsolete and pejorative term for a classification of mental retardation in which individuals have a mental age of less than 3 years.

idiotropic Egocentric or introspective.

idiot-savant Mentally retarded person who is able to perform unusual mental feats in sharply circumscribed intellectual areas, such as complicated calculations or puzzle solving.

I-It Philosopher Martin Buber's description of damaging interpersonal relationships. If a person treats themself or another person exclusively as an object, they prevent mutuality, trust, and growth. When pervasive in a group, I-It relationships prevent human warmth, destroy cohesiveness, and retard group process. *Compare* I-Thou.

illness anxiety disorder Preoccupation with being sick or developing a disease with few or no somatic symptoms and an absence of related pathologies found on medical examination. Differentiated from somatic symptom disorder (hypochondriasis) by the absence of somatic symptoms or complaints; patients with illness anxiety disorder are primarily concerned with "the idea" of being or becoming sick; a DSM-5 diagnosis. *Compare* somatic symptom disorder.

illogicality Pattern of speech or thinking in which conclusions that are reached do not follow logically; may take the form of unwarranted or faulty inferences.

illogic thinking Thinking containing erroneous conclusions or internal contradictions; psychopathologic only when it is marked and not caused by cultural values or intellectual deficit.

illuminism State of hallucinations in which a patient converses with imaginary supernatural creatures.

illusion Perceptual misinterpretation of a real external stimulus. *Compare* hallucination.

imago Jungian term referring to an idealized unconscious mental image of a key person in someone's early life.

imbecile Obsolete and pejorative term for a classification of mental retardation in which individuals have a mental age of 3 to 7 years.

imitation Duplication or mimicking of behaviors or portions of behaviors observed in a model. *See also* identification.

immediate memory Reproduction, recognition, or recall of perceived material within seconds after presentation. *Compare* long-term memory; short-term memory.

impaired insight Diminished ability to understand the objective reality of a situation.

impaired judgment Diminished ability to understand the objective reality of a situation. *See also* judgment.

implosion Behavior therapy technique in which anxiety-arousing stimuli are vividly presented in imagination; the patient repeatedly experiences intense anxiety in the absence of objective danger until the anxiety response is extinguished.

impotence A term used to refer to the inability to obtain an erection. In DSM, it is diagnosed as erectile disorder.

imprinting Particular kind of learning that occurs during an early critical developmental stage in animals, characterized by rapid acquisition and great resistance to extinction. It seems to represent a biologically predetermined proclivity to learn certain persistent species-specific behavior patterns, give exposure to the proper stimulus during the critical stage, but its precise role in human behavioral development has not been established.

improvisation In psychodrama, the acting out of situations without prior preparation.

impulse Psychic striving or urge to perform an action. *See also* drive; instinct.

impulse control Ability to resist an impulse, drive, or temptation to perform some action.

impulse-control disorders Mental disorders in which there is weak impulse control with impulsive behavior that is usually irresistible, pleasurable, and aimed at obtaining immediate gratification, without regard for the consequences of the behavior, for example, pathologic gambling, kleptomania, pyromania, intermittent explosive disorder, trichotillomania.

impulsion Blind following of internal drives without regard for social acceptance or pressure from the superego, normally seen in young children. In adults, it is common in those with weak defensive organizations; in such cases it tends to be a symbolic phenomenon.

inappropriate affect Emotional tone out of harmony with the idea, thought, or speech accompanying it. Seen in schizophrenia.

incest Sexual activity between close blood relatives. Common patterns are father–daughter, mother–son, and between siblings; may also be same sex.

incidence Research term for the number of cases of a disease whose onset occurs during a specific period of time. *See also* prevalence.

incidence rate Rate at which new cases of a disease or a condition are occurring. The incidence rate per 1,000 persons in the population is the number of new cases that occur within a defined unit of time, divided by the persons exposed or at risk during the same time unit, multiplied by 1,000.

incoherence Communication that is disconnected, disorganized, or incomprehensible. *See also* word salad.

incompetence Legal term indicating that thought processes are inadequate for sound judgment and may lead to maladaptive or abnormal behavior; legally, incompetent persons cannot be held responsible for their actions.

incorporation Primitive unconscious defense mechanism in which the psychic representation of another person or aspects of another person are assimilated into oneself through a figurative process of symbolic oral ingestion; represents a special form of introjection and is the earliest mechanism of identification.

increased libido Increase in sexual interest and drive. Often associated with mania.

independent variable In research methodology, those qualities that the experimenter systematically varies, for example, time, dosage.

individual psychology System of psychiatric theory developed by Alfred Adler that stresses compensation and overcompensation for feelings of inferiority in a person's strivings to adapt to the social milieu, and emphasizes the interpersonal nature of a person's problems; applied by some practitioners to group psychotherapy and counseling.

individual therapy Traditional dyadic therapeutic technique in which a psychotherapist treats only one patient during a given therapeutic session.

individuation Jungian term denoting a process whereby the person molds and develops a healthy integrated individual personality through maximum differentiation and development of each system of the personality. *See also* actualization.

Indoklon therapy Type of biologic therapy in which a convulsive seizure is induced by the inhalation of the drug Indoklon (hexafluorodiethyl ether).

indolamine Class of biogenic amines that contain an indole ring and are derived from the essential amino acid tryptophan; includes lysergic acid diethylamide (LSD) and serotonin. Monoamine oxidase inhibitors elevate the levels of indolamines by delaying their breakdown.

induced psychotic disorder *See* shared psychotic disorder.

industrial psychiatry Branch of psychiatry concerned with workers' adjustments to their jobs and with the effects of a business organization on its members.

ineffability Ecstatic state in which a person insists that their experience is inexpressible and indescribable, that it is impossible to convey what it is like to one who never experienced it.

infancy Childhood period of helplessness and marked dependency, generally the first year of life.

infantile articulation DEVELOPMENTAL ARTICULATION DISORDER.

infantile autism A term now subsumed under autism spectrum disorder that refers to a syndrome beginning in infancy and characterized by withdrawal and self-absorption, failure to develop attachment to a parental figure, ineffective communication and mutism, preoccupation with inanimate objects, and an obsessive demand for sameness in the environment. Also called Kanner syndrome; autistic spectrum disorder. *See also* autistic thinking.

infantile dynamics Psychodynamic integrations, such as the Oedipus complex, that are organized during childhood and continue to exert an unconscious influence on adult personality.

infantile perseveration DEVELOPMENTAL ARTICULATION DISORDER.

infantile sexuality Freudian concept regarding the erotic life of infants and children, that, from birth, infants are capable of erotic activities; encompasses the overlapping phases of psychosexual development during the first 5 years of life and includes the oral phase (birth to 18 months), the anal phase (ages 1 to 3), and the phallic phase (ages 2 to 6).

infant psychiatry That aspect of child psychiatry concerned with the diagnosis, treatment, and prevention of maladaptive psychological functioning in infants.

inferential statistics Methods used for drawing general conclusions about probabilities on the basis of a sample. *See also* statistical inference.

inferiority complex Concept, originated by Alfred Adler, that everyone is born with a feeling of inferiority or inadequacy secondary to real or fantasied organic or psychological deficits; how the inferiority or feeling of inferiority is handled determines a person's behavior in life. *See also* masculine protest.

informal admission As a general hospital model, a patient admitted to a psychiatric unit is free to enter and to leave, even against medical advice.

information theory System dealing with the transmission, reception, and distortion of communicated messages.

informed consent Consent given by a patient to a physician to perform a procedure legally requires that the patient be informed of the nature of the proposed procedure, its risks, its proposed benefits, and the available alternatives; the major problem in giving informed consent, legally and psychologically, is the extent or depth of disclosure.

infradian rhythm *See* biologic rhythm.

infusion Introduction of fluid other than blood, for example, medicines, into a vein.

inhalant Substance taken in by breathing. Production of psychoactive effects by the ingestion of such volatile substances as gasoline, airplane glue, aerosols (especially spray paints), or rubber cement, warrants the DSM diagnosis of inhalant dependence or inhalant abuse.

inhibited female orgasm Recurrent and persistent inhibition (absence) of the female orgasm, referring to the inability of a female to achieve orgasm by masturbation or coitus. Also called anorgasmia.

inhibited male orgasm Difficulty or inability of a male in achieving ejaculation during coitus. Also called ejaculatory incompetence; retarded ejaculation. *See also* primary retarded ejaculation; secondary retarded ejaculation.

inhibited sexual excitement Former term for female sexual arousal disorder.

inhibition Limitation or renunciation of ego functions occurring consciously, alone or in combinations, to evade anxiety arising out of conflict with instinctual impulses, the superego, or environmental forces or figures.

initial insomnia Falling asleep with difficulty; usually seen in anxiety disorder. *Compare* middle insomnia; terminal insomnia.

insane Of or pertaining to one who is of unsound mind. A legal rather than a psychiatric term.

insanity Legal concept denoting a mental disturbance, due to which a person lacks criminal responsibility for an alleged crime and hence cannot be convicted of the crime. *See also* American Law Institute formulation of insanity; Durham rule; M’Naghten rule.

insanity defense Criminal law defense plea that a person lacks criminal responsibility by reason of insanity.

insecurity Feelings of helplessness, unprotectedness, and inadequacy in the face of manifold anxieties arising from uncertainty regarding one’s goals, ideals, abilities, and relations to others.

insight Conscious recognition of one’s own condition. In psychiatry, it more specifically refers to the conscious awareness and understanding of one’s own psychodynamics and symptoms of maladaptive behavior; highly important in effecting changes in the personality and behavior of a person.

insight-oriented psychotherapy Psychotherapy based on the principles of psychoanalysis in which persons develop a conscious awareness and understanding of their own psychodynamics and symptoms of maladaptive behavior. There is greater emphasis on day-to-day reality issues and a lesser emphasis on the development of transference issues than in psychoanalysis.

insight therapy *See* insight-oriented psychotherapy.

insomnia disorder Difficulty in falling asleep or difficulty in staying asleep. It can be related to another mental disorder (nonorganic), can be related to a known organic factor (such as a physical disorder or a medication), or can be primary (not related to a known organic factor or to another mental disorder). *See also* initial insomnia; middle insomnia; terminal insomnia.

instinct Basic inborn urge or drive. Freud postulated the existence of two opposing primal instincts: a life instinct (eros) and a death instinct (thanatos). An extensive array of human instincts has been proposed, including possessive instinct, mastery instinct, and herd or social instinct. Because of its implication of a fixed, essentially unalterable, largely hereditary response or psychic tendency that does not involve learning or reason, the term has become ambiguous and controversial when applied to human behavior. Many modern psychoanalysts prefer the term “drive” for what Freud termed “instinct.” *See also* drive.

institutionalization Process of placing a patient in a facility for extended care, for example, a mental hospital or nursing home.

instrumental conditioning OPERANT CONDITIONING. *See* conditioning.

insulin coma therapy (ICT) Type of biologic therapy in which large amounts of insulin are given to a psychotic patient, usually a schizophrenic, producing profound hypoglycemia and resulting in a coma; introduced by Manfred Sakel in 1933, it declined in use drastically after the introduction of antipsychotic drugs. An occasionally used early stage of this treatment is called subcoma therapy.

intake Initial interview between a patient and a member of a psychiatric team, a term usually used in connection with admission to a mental health facility.

integration Constructive organizing, absorbing, and incorporating into the personality of data and experience; also refers to an amalgamation of separate parts into a functioning integral whole.

intellectual disability (ID) or intellectual developmental disorder Below average general intellectual functioning with concurrent impairment in adaptive behaviors, such as communication, self-care, and interpersonal skills, which manifests before adulthood. In DSM-5, the degree of ID is classified as mild, moderate, severe, or profound based on overall level of functioning. Previously called mental retardation.

intellectual insight Knowledge of the reality of a situation without the ability to successfully use that knowledge to effect an adaptive change in behavior. *Compare* true insight.

intellectualization Unconscious defense mechanism in which reasoning or logic is used in an attempt to avoid confrontation with an objectionable impulse and thus defend against anxiety. Also called brooding compulsion; thinking compulsion.

intellectual subaverage functioning IQ of more than two standard deviations below the test mean obtained on an intelligence test.

intelligence Capacity for learning and ability to recall, integrate constructively, and apply what one has learned; the capacity to understand and to think rationally.

intelligence quotient (IQ) Numerical measure of mental capability determined by dividing a mental age (MA) score achieved on a specific test, such as the Stanford–Binet Test, by the patient’s chronologic age (CA) and multiplying by 100.

intermission In psychiatry, the interval between attacks of a particular syndrome; when it is not certain that the symptoms will return, the interval is called a remission.

intermittent explosive disorder Condition in which a person has discrete episodes of losing control of aggressive impulses resulting in serious assault or destruction of property; often caused by a disorder of brain physiology, particularly in the limbic system.

intermittent reinforcement Any schedule of reinforcement in which the response is not always reinforced.

***International Classification of Diseases* (ICD)** World Health Organization's official list of disease categories subscribed to by all WHO member nations. ICD-CM is ICD's clinical modification, first published in 1919.

internship First year of clinical training following medical school, now called postgraduate year I (PGY-I), which progresses onto residency training in a specialty area.

interobserver reliability Degree of concurrence or disagreement among observers of a single event.

interpersonal conflict EXTRAPSYCHIC CONFLICT.

interpersonal psychiatry Dynamic-cultural system of psychiatry based on Harry Stack Sullivan's interpersonal theory, which proposes that each person must be viewed as an entity interacting with the sociocultural and interpersonal environment; emphasis is on interactive experiences.

interpersonal psychotherapy A type of brief psychotherapy used primarily for the treatment of depression. In a course of 10 to 12 sessions the therapist and patient focus of current problems with person in the environment which increases the patient's perception of self-defeating behaviors that contribute to low self-esteem and depression.

interpersonal skill Effectiveness of adaptive behavior in relation to other persons; ability to express feelings appropriately, to be socially responsible and responsive, and to work in harmony with others.

interpretation The formulation or description by the therapist to the patient of the therapist's understanding of the symbolic significance or meaning of any aspect of the patient's intrapsychic processes, behavior, or verbal productions; an attempt is made to construct into a more meaningful form the patient's resistances, defenses, transferences, and other symbolic activities, for example, dreams, fantasies.

Interpretation of Dreams The Sigmund Freud's major presentation (1899) not only of his theories about the meaning of dreams, a subject hitherto regarded as outside scientific interest, but also of his concept of a mental apparatus topographically divided into unconscious, preconscious, and conscious areas.

interview Person-to-person interaction in which information about a subject is collected. *See also* structured interview; unstructured interview.

intoxication Organic mental disorder due to the recent ingestion or presence in the body of an exogenous substance producing maladaptive behavior by virtue of its effects on the central nervous system. The most common psychiatric changes involve disturbances of perception, wakefulness, attention, thinking, judgment, emotional control, and psychomotor behavior; the specific clinical picture depends on the nature of the substance ingested. For types of intoxication, see the specific term.

intrapersonal conflict INTRAPSYCHIC CONFLICT.

intrapsychic Referring to what originates, takes place, or is situated within the psyche or mind.

intrapsychic ataxia *See* ataxia.

intrapsychic conflict State of tension arising from the clash of two or more incompatible or opposing forces; for example, wishes, needs, motives, thoughts operating within oneself. Also called intrapersonal conflict. *Compare* extrapsychic conflict.

intravenous Denoting introduction of a substance into a vein or veins. *See also* infusion.

introjection Unconscious, symbolic internalization of a psychic representation of a hated or loved external object with the goal of establishing closeness to and constant presence of the object; considered an immature defense mechanism. In the case of a loved object, anxiety consequent to separation or tension arising out of ambivalence toward the object is diminished; in the case of a feared or hated object, internalization of its malicious or aggressive characteristics serves to avoid anxiety by symbolically putting those characteristics under one's own control. *See also* incorporation.

intropunitive Turning anger inward toward oneself; commonly observed in depressed patients.

introspection Contemplating one's own mental processes so as to achieve insight.

introversion State in which a person's energies are directed inward toward the self, with little or no interest in the external world. *Compare* extroversion.

introverted personality disorder SCHIZOID PERSONALITY DISORDER.

inversion Sigmund Freud's term for homosexuality, in which he distinguished three types: absolute, amphigenous, and occasional.

involuntary admission Hospitalization of a person against their will. Following an application by a friend or relative for the admittance of a person who does not recognize the need for hospital care, certification by two physicians is required, which allows the patient to be hospitalized for 60 days. Patients have access to legal counsel and, if brought to court, a judge can order the patient's release. After 60 days, the case must be reviewed by a board (of psychiatrists, physicians, lawyers, and citizens not affiliated with the hospital). *See also* parens patriae.

involuntary discharge Termination of hospitalization against a patient's will.

involuntary treatment Care of a person, who has a mental disorder that constitutes a danger to self or others, against that person's will.

involutional melancholia Depression occurring in late middle-age in persons who generally have no history of previous mental illness. Characteristic manifestations include delusions of sin, guilt, or poverty; an obsession with death; preoccupation with somatic (particularly gastrointestinal) function; despair, dejection, agitation, anxiety, and insomnia; and, in some cases, paranoid ideation. The term is not used in DSM-5, but is replaced by the diagnosis of major depressive episode, melancholic type. Also called involutional psychosis.

involutional psychosis *See* involutional melancholia.

IQ Intelligence quotient.

irregular sleep phase circadian rhythm disorder A circadian rhythm sleep–wake disorder characterized by a fragmented, disorganized, or unpredictable sleep–wake pattern.

irrelevant answer Answer that is not responsive to the question.

irresistible impulse Concept that a person charged with a criminal offense is not responsible for their act if the act was committed under an impulse that the person was unable to resist because of mental disease. The courts have chosen to interpret this law in such a way that it has been called the "policeman-at-the-elbow" law; in other words, the court will grant the impulse to be irresistible only if it determines that the accused would have gone ahead with the act even if they had had a policeman at their elbow.

irritability Abnormal or excessive excitability, with easily triggered anger, annoyance, or impatience.

irritable mood State in which one is easily annoyed and provoked to anger. *See also* irritability.

isolated explosive disorder Disorder of impulse control in which a person has a single episode characterized by a failure to resist a violent impulse against others.

isolation In psychoanalysis, a defense mechanism involving the separation of an idea or memory from its attached feeling tone; unacceptable ideational content is thereby rendered free of its disturbing or unpleasant emotional charge. *Compare* relatedness. *See also* alienation.

isophilic Term used by Harry Stack Sullivan to mean liking or feeling affectionate toward people of the same sex, without the sexual or erotic aspects of homosexuality.

I-Thou Philosopher Martin Buber's conception that a person's identity develops from the true sharing by persons; basic trust can occur in a living partnership in which each member identifies the particular real personality of the other in their wholeness, unity, and uniqueness. In groups, I-Thou relationships promote warmth, cohesiveness, and constructive group process. *Compare* I-It.

J

jacksonian epilepsy Epilepsy characterized by recurrent episodes of focal motor seizures that usually begin with a highly localized tonic contraction or clonic movement which increases in severity and spreads progressively, often involving the entire body and terminating in a characteristic generalized convulsion with loss of consciousness; implies organic cerebral disease.

jamais vu Paramnestic phenomenon characterized by a false feeling of unfamiliarity with a real situation that one has experienced.

James–Lange theory of emotion Theory that the experience of emotion is preceded by a visceral or motor response, for example, first the person runs and then feels fear.

Janet, Pierre (1859–1947) Last great representative of the French school of psychiatry, known for his concept of psychological automatism and for his interest in cases of multiple personalities; first used the term “la belle indifférence.”

jargon aphasia Aphasia in which the words produced are neologistic, that is, nonsense words created by the patient.

JCAHO Joint Commission on Accreditation of Healthcare Organizations. Formerly JCAH, Joint Commission on Accreditation of Hospitals.

JCMHC Joint Commission on Mental Health of Children.

Joint Commission on Accreditation of Healthcare Organizations (JCAHO) Group of agencies that influence the standards and performance of hospitals and health organizations; they inspect hospitals every 2 years and determine requirements for hospital accreditation (on which hospital reimbursements from Medicare and Medicaid are contingent).

Joint Commission on Mental Health of Children (JCMHC) Multidisciplinary agency authorized by U.S. Congress in 1965 to monitor the treatment of children with emotional illness.

Joint Commission on Mental Illness and Health Multidisciplinary study group established in 1955 whose “Action for Mental Health”

(1961) was instrumental in the legislation and federal funding for community mental health centers; with the passage of the Community Mental Health Centers Act in 1963, deinstitutionalization became a reality.

Jones, Ernest (1879–1958) Welsh psychoanalyst, and one of Freud's early followers, who was an organizer of the American Psychoanalytic Association (1911) and of the British Psychoanalytical Society (1919) and a founder and long-time editor of the journal of the International Psychoanalytical Association; a prolific author most noted for his three-volume biography of Sigmund Freud.

judgment Mental act of comparing or evaluating choices within the framework of a given set of values for the purpose of electing a course of action. If the course of action chosen is consonant with reality or with mature adult standards of behavior, judgment is said to be intact or normal; judgment is said to be impaired if the chosen course of action is frankly maladaptive, results from impulsive decisions based on the need for immediate gratification, or is otherwise not consistent with reality as measured by mature adult standards.

Jung, Carl Gustav (1875–1961) Swiss psychiatrist and psychoanalyst, originally associated with Sigmund Freud, who later founded the school of analytic psychology.

justice In the context of mental health, a fair distribution and application of psychiatric procedures.

K

Kanner syndrome INFANTILE AUTISM.

kindling effect Electrophysiologic process in which repeated subthreshold stimulation of a neuron eventually generates an action potential; at the organ level, repeated subthreshold stimulation of an area of the brain results in the generation of a seizure.

kinesiology Study of body movement, especially in the context of its communicative function.

kinesthetic hallucination Hallucination primarily involving bodily movement.

kinesthetic sense Sense by which muscular motion, tension, position, and posture are perceived. Also called proprioception.

Kirkbride, Thomas S. (1809–1883) American psychiatrist, one of the 13 original founders of the American Psychiatric Association, noted for his 1854 manual advocating reform in the design of institutions for the mentally ill.

Klein, Melanie (1882–1960) British psychoanalyst and child analyst whose theories of early development departed from orthodox freudian thought.

Kleine–Levin syndrome Condition characterized by periodic episodes of hypersomnia and bulimia.

kleptomania Pathologic compulsion to steal.

Klinefelter syndrome Chromosomal anomaly in which there is an extra X chromosome (karyotype 47-XXY). Affected persons are male in development, with small firm testes, eunuchoid habitués, variable gynecomastia and other signs of androgen deficiency, and elevated gonadotropin levels; there is an increased frequency of mental retardation (about 25%) and other forms of psychopathology, particularly antisocial behavior and delinquency. *See also* Turner syndrome.

Klüver–Bucy syndrome Behavioral syndrome, first described in monkeys after bilateral temporal lobe ablation, characterized by increased oral, sexual, and aggressive behavior; loss of visual recognition: memory defect; and hyperreactivity to visual stimuli.

Kohut, Heinz (1913–1981) Important innovator in psychoanalysis, who originated the psychoanalytic school of self-psychology, which requires that patients become aware of their excessive needs for approval and self-gratification.

koro Acute delusional syndrome, seen in Southeast Asia and southern China, in which the patient suddenly becomes acutely anxious that his penis is shrinking and may disappear into his abdomen, in which case he will die.

Korsakoff psychosis Mental disorder seen in long-term alcoholics. Its major characteristic feature is profound memory impairment, particularly for recent events, for which the individual attempts to compensate by confabulation. Called alcohol amnestic disorder in DSM. *See also* Wernicke fluent encephalopathy.

Kraepelin, Emil (1865–1926) German psychiatrist noted for his pioneering work in psychiatric nosology and classification systems, and who differentiated between manic–depressive psychoses and dementia precox (schizophrenia). One of the last representatives of the predynamic school of psychiatry, he is often considered the father of descriptive psychiatry.

Kretschmer, Ernest (1888–1964) German psychiatrist noted for his theories of the relation of physique to character and personality.

kuru A prion disease, seen in Papua, New Guinea, caused by cannibalistic funeral rituals.

L

la belle indifférence Inappropriate attitude of calm or lack of concern about one’s disability; seen in patients with conversion disorder.

labile Unstable; characterized by rapidly changing emotions.

labile affect Affective expression characterized by repetitious and abrupt changes, unrelated to external stimuli.

labile mood Oscillations in mood between euphoria and depression or anxiety.

lability *See* emotional lability.

laconic speech Condition characterized by a reduction in the quantity of spontaneous speech; replies to questions are brief and unelaborated, and little or no unprompted additional information is provided. Occurs in major depression, schizophrenia, and organic mental disorders. Also called poverty of speech.

lacunar amnesia LOCALIZED AMNESIA.

lalophobia Abnormal fear of speaking. Also called glossophobia.

language disorder Persistent difficulties in the acquisition and use of language across modalities due to deficiencies in production (expressive) or comprehension (receptive-expressive) that include reduced vocabulary, difficulty with sentence formation, and impairments in discourse. Disorders lead to functional limitations in effective communication, social participation, and/or occupational performance. *See also* communication disorder.

lanugo Neonatal-like body hair; may be noted in anorexia nervosa.

lapsus linguae Slip of the tongue.

latah Culture-specific disorder found among Malaysians and characterized by either a sudden onset of unusual and inappropriate motor and verbal manifestations or by an echo reaction, in which the victim is compelled to imitate any words or actions to which they are exposed; in both forms affected persons cannot control or inhibit their behavior.

late language emergence DSM-5 disorder of early childhood characterized by delayed language onset in the absence of any developmental disabilities or delays.

late luteal phase dysphoric disorder (LLPDD) *See* premenstrual dysphoric disorder.

latency phase Period of psychosexual development after the phallic phase and succeeded by the genital phase, extending from about age 5 to the beginning of adolescence at age 12; during this phase there is an apparent cessation of sexual preoccupation and a blockade of libidinal impulses, and boys and girls are inclined to choose friends and join groups of their own sex.

latent content Hidden or unconscious meaning of symbolic representations, especially in fantasies and dreams. *See also* manifest content.

latent homosexuality Unexpressed conscious or unconscious homoerotic wishes that are held in check. Sigmund Freud’s theory of bisexuality postulated the existence of a constitutionally determined, although experientially influenced, instinctual masculine–feminine duality; normally, the opposite-sex component is dormant, but a breakdown in the defenses of repression and sublimation may activate latent instincts and result in overt homoeroticism.

latent schizophrenia Condition characterized by clear schizophrenic symptoms without a history of prior overtly psychotic schizophrenic episodes. In DSM the condition is subsumed under the category of schizotypal personality disorder.

learned autonomic control Learned regulation by a person of physiologic responses that are under autonomic nervous system control. *See also* biofeedback.

learned helplessness *See* helplessness.

learning disorders Disorders manifested in school-age children and characterized by specific difficulties in learning that are unrelated to intelligence. In DSM, disorders include reading disorder, dyscalculia, and disorder of written expression. *See also* dyslexia.

learning theory Approach to the understanding of human behavior that emphasizes the way in which learning comes about. Learning itself represents a change in behavior resulting from practice; through the application of certain laws of learning, learning theory attempts to explain the basic processes that are necessary for learning to occur.

lesbianism Female homosexuality. Also called sapphism.

Lesch–Nyhan syndrome A rare, X-linked disorder caused by a deficiency of an enzyme involved in purine metabolism. Characteristics include intellectual disability, seizures, self-mutilating behaviors (e.g., head banging, finger biting), microcephaly, choreoathetosis, and spasticity.

lethologica Momentary forgetting of a name or proper noun. *See* blocking.

leukotomy LOBOTOMY.

Lewin, Kurt (1890–1947) German psychologist who emigrated to United States in 1933. Two of his chief theoretical contributions are the field approach (field theory) and group dynamics, each of which has been useful in the experimental study of human behavior in a social situation.

Lewy body disease A type of dementia clinically similar to Alzheimer disease that is also accompanied by hallucinations and parkinsonian features. Often associated with Capgras syndrome. *See also* dementia of the Alzheimer type.

Liaison Committee on Medical Education (LCME) Group sponsored by the American Medical Association and the Association of American Medical Colleges that is principally involved in accrediting activities in undergraduate medical education.

liaison nursing Communication among nurses from various disciplines concerning the treatment of medical, surgical, and neuropsychiatric patients.

liaison psychiatry *See* consultation-liaison psychiatry.

libido In psychoanalysis, the psychic energy associated with the sexual drive (life instinct).

life instinct SEXUAL DRIVE.

lifetime expectancy Total probability of a person developing a disorder during a lifetime.

lifetime prevalence Measure at a point in time of the number of persons who had a given disorder at some time during their lives.

lilliputian hallucination Visual sensation that persons or objects are reduced in size, more properly regarded as an illusion. *See also* micropsia.

limbic system James Papez' proposal (1939) that a reverberating circuit or system, consisting of the hippocampus, hypothalamus, anterior thalamus, and cingulate gyrus, was the central nervous system localization for emotions; current models also include the amygdala and septal area, as well as other neuroanatomic areas. Various parts of the limbic system have been associated with emotions, sex drive, eating behavior, rage, violence, memory, and motivation.

lithium carbonate Lithium salt effective in the treatment of the manic phase of bipolar disorder and as a mood-stabilizing drug for chronic manic–depressive patients; may also be an effective antidepressant in some patients.

Little Albert Eleven-month-old boy who was conditioned to fear furry objects in experiments conducted by American psychologist John B. Watson (1920) to demonstrate that phobias are learned responses based on classical conditioning.

Little Hans Sigmund Freud's famous case history of a 5-year-old boy with a phobia. The boy's fear of horses, instead of his father, helped him to avoid hating his father, by whom he was threatened; and whom he also loved.

living will Legal document in which patients gives instructions to their physicians about withholding life support measures, for example, Do Not Resuscitate (DNR) if in extremis.

LCME Liaison Committee on Medical Education.

LLPDD Late luteal phase dysphoric disorder.

LNNB Luria-Nebraska Neuropsychological Battery.

lobotomy Neurosurgical procedure, introduced by Egas Moniz, in which one or more nerve tracts in a lobe of the cerebrum are severed. Prefrontal lobotomy is the ablation of one or more nerve tracts in the prefrontal area of the brain and has been used in the treatment of certain severe mental disorders that do not respond to other treatments. Also called leukotomy.

localized amnesia Partial loss of memory; amnesia restricted to specific or isolated experiences. Also called lacunar amnesia; patch amnesia.

locus ceruleus Nucleus (a collection of neuronal cell bodies) that is located in the pons (a region of the brain stem) and contains the largest population of noradrenergic neurons in a single identified brain region; these neurons project their axons to virtually every region of the brain and are thought to be involved in the regulation of mood, anxiety, and attention.

logorrhea Copious, pressured, coherent speech; uncontrollable, excessive talking; observed in manic episodes of bipolar disorder. Also called tachylogia; verbomania; volubility.

logotherapy Existential analysis based on spiritual values, rather than psychobiologic laws.

longitudinal study Examination or analysis carried out of a long period of time.

long-term memory Reproduction, recognition, or recall of experiences or information that were experienced in the distant past. Also called remote memory. *Compare* immediate memory; short-term memory.

loosening of associations Characteristic schizophrenic thinking or speech disturbance involving a disorder in the logical progression of thoughts, manifested as a failure to adequately verbally communicate; unrelated and unconnected ideas shift from one subject to another. *See also* tangentiality.

Lou Gehrig disease AMYOTROPHIC LATERAL SCLEROSIS.

LP Lumbar puncture.

LSD Lysergic acid diethylamide.

Lumbar puncture (LP) Use of a needle inserted into the lumbar spine intervertebral space to obtain cerebrospinal fluid for diagnostic purposes or to introduce local anesthetics or other drugs.

Luria-Nebraska Neuropsychological Battery (LNNB) Based on the work of the Russian psychologist A. R. Luria, the test assesses a wide range of cognitive functions: memory; motor functions; rhythm; tactile, auditory, and visual functions; receptive and expressive speech; writing; spelling; reading; and arithmetic. It is extremely sensitive for identifying specific types of problems (e.g., dyslexia, dyscalculia) rather than being limited to more global impressions of brain dysfunction; it also helps localize the various cortical zones that are involved in a particular function and is useful in establishing left or right cerebral dominance. The test is designed for persons at least 15 years of age; a children's version for use with 8 to 12 year olds is being developed.

lust dynamism Harry Stack Sullivan's term to describe clearly stated sexual desires and abilities.

lying Making statements that one knows consciously are false with intent to deceive; differentiated from confabulation, in which one is not conscious of lying.

lysergic acid diethylamide (LSD) A potent psychotogenic drug discovered in 1942 that produces psychotic-like symptoms and behavior changes, including hallucinations, delusions, and time-space distortions. Commonly called acid.

M

macropsia False perception that objects are larger than they really are. *Compare* micropsia.

magical thinking A form of dereistic thought; thinking similar to that of the preoperational phase in children (Jean Piaget), in which thoughts, words, or actions assume power (e.g., to cause or to prevent events). Common in dreams, certain mental disorders, and children.

magnetic resonance imaging (MRI) Diagnostic modality in which a patient's body is placed in a magnetic field and its hydrogen nuclei are excited by radiofrequency pulses at angles to the field's axis; resulting signals from the body's hydrogen ions are processed through a computer to produce an image; an excellent method for differentiating gray and white matter, visualizing cerebrospinal fluid, and estimating the size of ventricles.

Mahler, Margaret (1897–1985) Hungarian-born psychiatrist and child analyst who described the separation–individuation process in children.

maintenance drug therapy Stage in the course of chemotherapy at which, after the drug has reached its maximal efficacy, the dosage is reduced and sustained at the minimal therapeutic level that will prevent a relapse or exacerbation.

major affective disorder *See* major depression.

major depressive disorder Severe mood disorder characterized by one or more depressive episodes but no history of a manic episode; a DSM-5 diagnosis. *See also* mood disorder.

major depressive episode, melancholic type DSM diagnosis replacing involutional melancholia.

major epilepsy *See* grand mal epilepsy.

major motor seizure *See* grand mal epilepsy.

major neurocognitive disorder DSM-5 term for dementia.

major tranquilizer ANTIPSYCHOTIC.

maladaptive Referring to any mental activity or behavior that is dysfunctional or counterproductive with regard to a person's ability to cope effectively with the problems and stresses of life.

maladjustment Maladaptive reaction; poor, faulty, or inadequate coping ability.

male erectile disorder DSM sexual arousal disorder characterized by the recurrent and persistent partial or complete failure to obtain or maintain penile erection until the completion of the sex act. Also called erectile dysfunction. *See also* impotence.

male hypoactive sexual desire disorder Disorder characterized by an absence of or reduction in sexual fantasies and/or the desire for sexual activity in men

maleness Anatomic and physiologic features relating to the male's procreative functions.

malingering Feigning disease in order to achieve a specific goal, for example, to avoid an unpleasant responsibility. *Compare* factitious disorder.

malpractice Professional negligence including intentional or willful invasion of another's legally protected interests, such as battery or treatment without consent; must be demonstrated by the presence of *d*ereliction of a *d*uty *d*irectly causing *d*amages (the four D's of malpractice).

mania Mood abnormality characterized by elation; agitation; hyperactivity and hyperexcitability; accelerated thinking and speaking (flight of ideas); decreased need for sleep; and overinvolvement in pleasurable behavior. Characterizes the manic phase of bipolar I disorder when lasting more than a week or is severe enough to warrant hospitalization. *Compare* hypomania.

manic Denoting or characterized by mania. Sometimes used as a general description for a mentally disturbed person, often someone exhibiting violent or grossly irrational behavior.

manic–depressive illness Mood disorder characterized by severe alterations in mood that are usually episodic and recurrent. The unipolar type is characterized by either periodic episodes of mania (manic disorder) or periodic episodes of depression (depressive disorder). In the bipolar or circular type, the patient has at least one episode of each mood extreme and may alternate periodically between the two. Manic–depressive illness has been replaced by bipolar disorder in DSM.

manifest content That part of a dream or fantasy that a person remembers and reports; in a dream, it represents a disguised and symbolic expression of the latent content of the dream.

manipulation Exploitativeness; the maneuvering by patients to get their own way, characteristic of antisocial personalities.

mannerism Stereotyped gesture or expression that is peculiar to a given person.

mantra In transcendental meditation, a Sanskrit syllable or word that is repeated over and over in an effort to produce total relaxation and control over one's state of consciousness.

MAOI Monoamine oxidase inhibitor.

marasmus Progressive emaciation, especially in malnourished infants and children, in which weight is often below the third percentile and markedly below appropriate weight for height.

marathon Technique developed by George Bach and Frederick Stoller that incorporates a group meeting that usually lasts 8 to 72 hours (although some may last for a week), in which the sessions interrupted only for eating and sleeping; the leader works for the development of intimacy and the open expression of feelings. The time-extended group experience culminates in intense feelings of excitement and elation.

marijuana Dried leaves and flowers of *Cannabis sativa* (Indian hemp), which induce somatic and psychic changes in a person when smoked or ingested in sufficient quantity. Somatic changes include increased heart rate, rise in blood pressure, dryness of the mouth, and increased appetite; psychic changes include a dreamy-state level of consciousness, a sense of enhanced vividness of visual and auditory sensations, disturbances of time perception and memory-dependent, goal-directed behavior, disruptions of sequential thought processes, and euphoria and other alterations of mood. The compound believed to be responsible for most of its psychological effects is tetrahydrocannabinol (THC). In strong doses, marijuana can produce hallucinations and, at times, paranoid ideation. Also called pot; grass; weed; dope; Mary Jane.

marital counseling Process whereby a trained counselor helps married couples resolve problems that arise and trouble them in their relationship; the husband and the wife are seen by the same worker in separate and joint counseling sessions that focus on immediate family problems. The theory and techniques of this approach were first developed in social agencies as part of family case work.

marital problems Maladaptive behavior between spouses in various areas, for example, attitudes toward sex, contraception, child rearing, money handling.

marital therapy *See* marriage therapy.

marriage therapy Type of family therapy that involves the husband and the wife and focuses on the marital relationship as it affects the individual psychopathology of the partners. The rationale for the method is the assumption that psychopathologic processes within the family structure and in the social matrix of the marriage perpetuate individual pathologic personality structures, which find expression in the disturbed marriage and are aggravated by the feedback between partners.

masculine identity Inner sense of gender affiliation with males. *Compare* feminine identity.

masculine protest Adlerian doctrine that depicts a universal human tendency to move from a passive and feminine role to a masculine and active role; an extension of Alfred Adler's ideas about organic inferiority that became the prime motivational force in normal and neurotic behavior in his system. *See also* Adler, Alfred; inferiority complex.

masculinity–femininity scale Any scale on a psychological test that assesses the relative masculinity or femininity of the testee. Scales vary and may focus, for example, on basic identification with either sex or preference for a particular sex role and are strongly influenced by cultural definitions of masculinity and femininity.

masochism Paraphilia in which sexual gratification is derived from being physically or psychologically maltreated by a partner or oneself; first described by an Austrian novelist, Leopold von

Sacher-Masoch (1836–1895). *See also* sadism; sadomasochistic relationship.

masturbation Self-stimulation of the genitals for sexual pleasure. *See* autoerotism.

maternal deprivation Result of the premature loss or absence of the mother. In a broader sense, the lack of proper mothering may constitute a form of maternal deprivation which may lead to severe emotional disorders in infants and children.

maturational crises Normative stages of the life cycle that require adaptive coping or defense mechanisms.

maximum security unit That part of an institution for the mentally ill reserved for those who have committed crimes or who are considered dangerous to others.

MCE Medical care evaluation.

MDMA 3,4-Methylenedioxymethamphetamine.

mean Statistical measurement derived from adding a set of scores and then dividing by the number of scores. *See also* average.

mean deviation Statistical measure of the variability in a set of values defined as the sum of the absolute differences between the values and the mean divided by the number of values.

median Value in a set of values above and below which there are an equal number of values; for example, in the series 1, 3, 5, 9, 33 the value 5 is the median. *See also* average.

Medicaid Assistance program for certain needy and low-income persons, mandated by the federal government and financed by both federal and state governments; certain benefits, such as in- and outpatient hospital care, physicians' services, and laboratory tests, are required covered expenses, while other services may be provided at the state's option.

medical audit Retrospective assessment of the quality and utilization of care, including investigation of suspected problems, analysis of the problems identified, and a plan for corrective action. Also called medical care evaluation (MCE).

medical care evaluation (MCE) MEDICAL AUDIT.

medical ethics Moral set of principles that determine what is right or wrong and good or bad, as they pertain to professional responsibilities and opinions relating to the values of patients, patients' families, and society at large. For related issues, see the specific term.

medical record Written exposition describing a patient's diagnosis and treatment.

medical review Evaluation of the quality of care and assessment of medical care or services judged in terms of cost effectiveness.

Medicare Hospital and medical insurance system for the aged created in 1965 by amendments of the Social Security Act. Hospitalization in general hospitals for psychiatric conditions is covered in the same way as other conditions.

medication-induced movement disorders A group of disorders that include neuroleptic malignant syndrome, neuroleptic-induced parkinsonism, neuroleptic-induced acute akathisia, neuroleptic-induced tardive dyskinesia, neuroleptic-induced acute dystonia, and medication-induced postural tremor.

megalomania Morbid preoccupation with expansive delusions of power, importance, or wealth.

megavitamin therapy *See* orthomolecular treatment.

melancholia A severe depressive state characterized by anhedonia, early morning awakening, weight loss, psychomotor retardation, and profound feelings of guilt and hopelessness; often associated with suicidal ideation.

memory Process whereby what is experienced or learned is established as a record in the central nervous system (registration), where it persists with a variable degree of permanence (retention) and can be recollected or retrieved from storage at will (recall). For types of memory, see the specific term.

menarche Onset of menstrual function.

mendacity Pathologic lying.

mens rea Legal term meaning an intent to do harm.

mental aberration Pathologic deviation from normal thinking; unrelated to a person's intelligence.

mental age Measure of mental ability as determined by standard psychological tests.

mental deficiency Term often used interchangeably with mental retardation, applied to individuals with an IQ of less than 70. *See* intellectual developmental disorder.

mental disorder, mental disease Psychiatric illness or disease whose manifestations are primarily characterized by behavioral or psychological impairment of function, measured in terms of deviation from some normative concept.

mental health State of emotional well-being in which persons are able to function comfortably within their society and in which their personal achievements and characteristics are satisfactory to them.

mental hygiene 1. Conditions and practices conducive to the establishment and maintenance of mental health. **2.** Field dealing with the prevention and early treatment of mental illness. *See also* orthopsychiatry.

mental illness Mental disorder; any serious impairment of adjustment; any psychiatric disorder listed in the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* or in the World Health Organization's *International Classification of Diseases.*

mental retardation Term previously assigned to the condition that DSM-5 now refers to as intellectual disability. Degrees of condition were historically classified according to IQ: mild (50–55 to 70), moderate (35–40 to 50–55), severe (20–25 to 30), and profound (below 20–25). *See* intellectual disability.

mental status General functional condition of mental and behavioral processes as determined by psychiatric assessment of a variety of areas of functioning, such as state of consciousness, mood and affect, thinking and speech, motor behavior, general knowledge, memory, calculation, judgment, abstraction, and insight.

mental status examination (MSE) Clinical evaluation, and the sum total of the examiner's observations and impressions, of a person's psychological and behavioral experiences. MSE includes specific references to such areas as attitude and general behavior during interview and to sensorium, mental capacity, and other areas of function.

merycism RUMINATION DISORDER OF INFANCY.

mescaline Hallucinogenic drug obtained from buttons of the peyote cactus that has psychotomimetic effects similar to those of LSD.

mesmerism Early term for hypnosis.

mesomorphic Muscular, with a well-proportioned physique; one of Sheldon's constitutional types. *Compare* ectomorphic; endomorphic.

meta-analysis General consensus of many studies that results in one common data base that helps to eliminate bias.

metapsychiatry Branch of psychiatry concerned with altered state of consciousness, holistic health, and parapsychology.

metapsychology Branch of theoretical or speculative psychology concerned with theories, hypotheses, or phenomena that are largely beyond the realm of empirical verification. *See also* parapsychology.

methadone Orally active synthetic narcotic agent that is an effective analgesic with pharmacologic actions qualitatively very similar to those of morphine. Its use in the maintenance treatment of heroin addicts is based on its extended duration of action in suppressing withdrawal symptoms in persons physically dependent on opiates.

methadone maintenance treatment *See* methadone.

3-methoxy-4-hydroxyphenylglycol (MHPG) Most significant metabolic product from central nervous system norepinephrine; excreted in urine.

3,4-methylenedioxymethamphetamine (MDMA) Hallucinogen more commonly known as ecstasy.

methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) Contaminant of an illicitly made synthetic heroin that induces irreversible parkinsonism.

metonymy Speech disturbance common in schizophrenia in which the affected person uses a word or phrase that is related to the proper one but is not the precise one that would ordinarily be used; for example, the patient speaks of consuming a "menu," rather than a “meal,” or refers to losing the “piece of string” of the conversation, rather than the “thread” of the conversation. *See also* paraphasia; word approximation.

Metrazol treatment Obsolete form of convulsive therapy in which a convulsive seizure is induced by injection of the drug Metrazol (pentylenetetrazol).

Meyer, Adolf (1866–1950) American psychiatrist known for his concept of psychobiology and “commonsense” psychiatry.

MHPG 3-Methoxy-4-hydroxyphenylglycol.

microcephaly Condition in which the head is unusually small as a result of defective brain development and premature ossification of the skull.

micropsia False perception that objects are smaller than they really are. Sometimes called lilliputian hallucination. *Compare* macropsia.

MID Multi-infarct dementia.

middle age, middle adulthood That period considered to be the prime of life, between the ages of approximately 40 to 65 years, following the termination of early adulthood.

middle insomnia Waking up after falling asleep without difficulty and then having difficulty in falling asleep again. *Compare* initial insomnia; terminal insomnia.

midlife crisis Syndrome that occurs in both sexes as they enter their early 40s or 50s, consisting of depression, substance abuse, concern about growing old, and fear of death; more common in adults with prior psychiatric illness than in normal adults.

migraine Severe unilateral, throbbing headache that appears periodically, usually beginning during the teenage years and continuing to recur with diminishing frequency during advancing years. Classic migraine is a syndrome ushered in by a transient derangement of neurologic function, often a visual disturbance, followed by hemicranial headache, nausea, and vomiting, all of which last for anywhere from several hours to 1 or 2 days. Common migraine has the same character and time course but develops without any prodrome. Patients with migraine are typically described as tense, meticulous, hard-driving persons who appear to have a high frequency of associated emotional conflicts.

mild mental retardation *See* mental retardation.

mild neurocognitive disorder Mild decline in cognitive function that is differentiated from the normal cognitive changes associated with aging; memory is impaired for age and education, however, general cognitive function and activities of daily living remain intact. In DSM-5 diagnosed as mild neurocognitive disorder due to multiple etiologies or unspecified neurocognitive disorder.

milieu therapy Treatment that emphasizes appropriate socioenvironmental manipulation for the benefit of the patient; the setting is usually the psychiatric hospital. *See also* moral treatment; therapeutic community.

mimicry Simple, imitative motion activity of childhood.

minimal brain dysfunction Behavioral syndrome of childhood, now called attention-deficit hyperactivity disorder, characterized by learning difficulties, decreased attention span, distractibility, hyperactivity, impulsiveness, emotional lability, and, often, disturbances in perceptuomotor and language development; its psychopathologic mechanisms have not been defined. The term implies neurologic causation, but in most cases there are no major unequivocal neurologic signs and there has been a tendency to apply the term as a convenient explanatory label to any child presenting with a specific learning difficulty or behavioral dysfunction. Although the syndrome has been diagnosed with increasing frequency over the past 20 years, its validity as a diagnostic entity has been questioned, and it is not listed as such in DSM.

Minnesota Multiphasic Personality Inventory (MMPI) Questionnaire type of psychological test for persons age 16 and over consisting of true–false statements that are coded in various scales that assess different dimensions of the person's personality structure and measure the closeness of fit with various psychiatric diagnostic categories.

minor epilepsy PETIT MAL EPILEPSY.

minor tranquilizer ANXIOLYTIC.

Mitchell, S. Weir (1830–1914) American neurologist known for his concept of rest treatment to cure emotional disorders.

mixoscopia Sexual perversion in which a person attains orgasm by watching their love object make love with another person.

MMPI Minnesota Multiphasic Personality Inventory.

M'Naghten rule Set of rules established in 1843 in England to determine criminal responsibility, based on the person's ability to distinguish right from wrong. *See also* Durham rule; American Law Institute formulation of insanity.

mode In a set of measurements, the value that appears most frequently. *See also* average.

modeling Learning of a new skill or behavior by observation and imitation of another person.

Model Penal Code American Law Institute's test of criminal responsibility: "A person is not responsible for criminal conduct if at the time of such conduct, as a result of mental disease or defect, he lacked substantial capacity to either appreciate the criminality (wrongfulness) of his conduct or to conform his conduct to the requirement of the law."

moderate mental retardation *See* mental retardation.

molecular psychiatry Etiologic view of psychiatry based on neurotransmitter chemicals as measured in molecular quantities.

mongolism Obsolete and culturally offensive term for Down syndrome.

monoamine Biogenic amine or class of neurotransmitters that consists of three catecholamines (dopamine, norepinephrine, and epinephrine), an indolamine (serotonin), a quaternary amine (acetylcholine), and an ethylamine (histamine).

monoamine oxidase (MAO) Enzyme that deaminates monoamines and that functions, in the nervous system by breaking down monoamine neurotransmitters (e.g., norepinephrine, epinephrine, dopamine, and serotonin); has been subdivided into Type A and Type B.

monoamine oxidase inhibitor (MAOI) Agent that inhibits the enzyme monoamine oxidase (MAO). MAO inhibitors are highly effective as antidepressants and are also used in the treatment of panic disorders and some eating disorders.

monomania Morbid mental state characterized by preoccupation with one subject. Also called partial insanity.

monosymptomatic hypochondriacal psychosis A delusional disorder consisting of somatic delusions; common delusions include infestation, dysmorphophobia, and foul body odors or halitosis.

monozygotic twins Twins who develop from a single fertilized ovum. In contrast, dizygotic or fraternal twins develop from two separately fertilized ova. Also called identical twins.

mood Pervasive and sustained feeling tone that is experienced internally and that, in the extreme, can markedly influence virtually all aspects of a person’s behavior and their perception of the world. Distinguished from affect, the external expression of the internal feeling tone. For types of mood, see the specific term.

mood-congruent delusion Delusion with content that is mood appropriate, for example, a depressed patient who believes they are responsible for the destruction of the world.

mood-congruent hallucination Hallucination with content that is consistent with either a depressed or a manic mood, for example, a depressed patient hearing voices telling the patient they are a bad person; a manic patient hearing voices telling the patient they have inflated worth, power, or knowledge.

mood-congruent psychotic features DSM term that refers to hallucinatory or delusional phenomena with contents that consistently reflect the mood of a manic or depressed patient.

mood disorders Qualitative terms used to describe the striking symptomatic features or timing patterns in various patients with moods disorders. Descriptive qualifiers include psychotic, melancholic, atypical, and catatonic features; patterns include postpartum onset, rapid cycling, and seasonal pattern.

mood-incongruent delusion Delusion based on incorrect reference about external reality, with content that has no association to mood or is mood-inappropriate, for example, a depressed patient who believes they are the new Messiah.

mood-incongruent hallucination Hallucination not associated with real external stimuli, with content that is not consistent with either depressed or manic mood, for example, in depression, hallucinations not involving such themes as guilt, deserved punishment, or inadequacy; in mania, not involving such themes as inflated worth or power.

mood-incongruent psychotic features DSM term that refers to hallucinatory or delusional phenomena with contents that do not consistently reflect the mood of a manic or depressed patient.

mood stabilizer Drug used to prevent mood swings in bipolar disorder.

mood swing Oscillation of a person’s emotional feeling tone between periods of elation and periods of depression.

moral treatment Philosophy and technique of treating mental patients, developed in the 18th century, that involved the establishment of a humane therapeutic environment designed to maximize the chances for recovery; considered the forerunner of current milieu therapy.

morbid jealousy Marked or severe jealousy. Also called pathologic jealousy.

morbid perplexity Condition seen in schizophrenia in association with loss of ego boundaries; the patient exhibits profound confusion about his own identity and the meaning of existence.

moron Obsolete and pejorative term for a classification of mental retardation in which an individual has a mental age of approximately 8 years.

morphine Major phenanthrene alkaloid opium derivative that produces a combination of central nervous system excitation and depression; repeated administration can lead to tolerance, physical dependence, and psychological dependence; used as an analgesic, sedative, and anxiolytic.

Moses and Monotheism Title of a book by Sigmund Freud (1939) in which he undertook a historical but frankly speculative reconstruction of the personality of Moses and examined the concept of monotheism and the abiding effect of the patriarch on the character of the Jews; one of Freud's last works, it bears the imprint of his latter-day outlook and problems.

mother surrogate In psychoanalysis, a mother substitute onto whom a patient projects their mother image and responds to unconsciously, in an inappropriate and unrealistic manner, with the feelings and attitudes that they had toward the real mother.

motivation Force or energy associated with an internal state that propels a person to engage in behavior to satisfy a need or desire.

motor aphasia Aphasia in which understanding is intact but the ability to speak is lost. Also called Broca's, expressive, or nonfluent aphasia.

motor disorders A class of neurodevelopmental disorders defined by a delay in meeting expected milestones for motor skills, based on age and intelligence, which significantly impairs daily functioning. The major types of motor disorders include developmental coordination disorder, stereotypic movement disorder, and tic disorder.

mourning Syndrome following loss of a loved one, consisting of preoccupation with the lost individual, weeping, sadness, and repeated reliving of memories. *See also* bereavement; grief.

MPD Multiple personality disorder.

MPTP Methyl-4-phenyl-1,2,3,6-tetrahydropyridine.

MRI Magnetic resonance imaging.

multi-infarct dementia *See* vascular dementia.

multiple delusions Concurrent delusions in which the delusions need not be interconnected.

multiple personality disorder *See* dissociative identity disorder.

multiple regression Multivariate analysis in which a scaled variable is correlated with a linear combination of independent or predictor variables.

multiple therapy CO-THERAPY.

multivariate analysis Methods for considering the relationship of three or more variables, including multiple regression, multivariate analysis of variance, discriminant analysis, canonical correlation, and factor analysis.

Munchausen syndrome Alternate term for factitious disorder.

muscarine Naturally occurring alkaloid found in certain species of poisonous mushrooms; symptoms of mushroom poisoning develop within 30 minutes of ingestion and consist of vomiting, diarrhea, bronchospasm, hypertension, delirium, and shock.

mutism Organic or functional absence of the faculty of speech. *See also* stupor.

mydriasis Dilation of the pupil; sometimes occurs as an autonomic (anticholinergic) side effect of some phenothiazines and tricyclic antidepressant drugs.

mysophobia Abnormal fear of dirt or contamination.

N

naloxone Opiate antagonist that, unlike nalorphine which it has largely replaced as a narcotic antagonist is essentially devoid of agonist effects. In opioid-dependent persons, small doses of naloxone precipitate moderate to severe withdrawal symptoms, an effect that can be used to diagnose physical dependence on narcotic drugs; however, the most important use of naloxone is in the treatment of narcotic overdosage. (Trade name, Narcan.)

NAMI National Alliance for the Mentally Ill.

narcissism Self-love linked to autoerotism but devoid of geniality. In psychoanalytic theory, it is divided into primary and secondary types: primary narcissism, the early infantile phase of object relationship development, when the child has not differentiated the self from the outside world and all sources of pleasure are unrealistically recognized as coming from within the self, giving the child a false sense of omnipotence; secondary narcissism, when the libido, once attached to external love objects, is redirected back to the self. *See also* autistic thinking.

narcissistic personality disorder Personality disorder characterized by a grandiose sense of self-importance, preoccupation with fantasies of unlimited success, exhibitionistic need for attention and admiration, exaggerated responses to criticism or other perceived threats to self-esteem, and disturbance in interpersonal relationships.

narcoanalysis NARCOTHERAPY.

narcolepsy Sleep disorder characterized by recurrent, brief, uncontrollable episodes of sleep; often associated with cataplexy. *See also* hypersomnia.

narcosis Drug-induced stupor.

narcosynthesis NARCOTHERAPY.

narcotherapy Psychotherapy conducted with the patient in a drug-induced stupor or semiconscious state, as by the administration of barbiturates; originally used in the treatment of acute disorders arising in the setting of military combat; also called narcoanalysis; narcosynthesis.

narcotic Any natural or synthetic drug producing morphine-like analgesia, drowsiness, mental clouding, and, with prolonged use, physical dependence. *See also* opioid.

narcotic blockade Inhibition of the euphoric effects of even high doses of intravenous opioids, such as heroin, by the use of other drugs, such as methadone.

National Alliance for the Mentally Ill (NAMI) Self-help group and influential national advocacy network comprised of and supported by the family members and parents of schizophrenic patients.

National Board of Medical Examiners (NBME) National board, founded in 1915, for testing medical students by three examinations given during different stages of their medical education to qualify for licensure to practice medicine in the United States; the diploma is accepted in 50 states for obtaining licensure without further examination by the state.

National Center for Complementary and Alternative Medicine (NCAAM) A government agency, part of the National Institute of Health that tests and evaluated alternative medicine therapies, for example, nutritional supplements, prayer, yoga, among many others.

National Institute of Alcohol Abuse and Alcoholism (NIAAA) *See* Alcohol, Drug Abuse, and Mental Health Administration.

National Institute of Drug Abuse (NIDA) *See* Alcohol, Drug Abuse, and Mental Health Administration.

National Institute of Mental Health (NIMH) *See* Alcohol, Drug Abuse, and Mental Health Administration.

National Mental Health Association (NMHA) Voluntary citizens' organization, founded in 1909 as the National Committee on Mental Hygiene, to promote mental health.

National Training Laboratories (NTL) Organization started in 1947 at Bethel, Maine, to train professionals who work with groups; interest in personal development eventually led to sensitivity training and encounter groups.

natural group Any group that tends to evolve spontaneously in human civilization, such as a kinship, tribal, or religious group in contrast to various contrived groups or aggregates of people who meet for a relatively brief time to achieve some goal.

NBME National Board of Medical Examiners.

NCAAM National Center for Complementary and Alternative Medicine.

necromania Pathologic preoccupation with dead bodies.

necrophilia Sexual attraction to or sexual contact with dead bodies.

necrophobia Abnormal fear of dead bodies.

need Ambiguous term referring to an internal state of unsatisfaction or tension related to a wish, urge, desire, or other endogenous behavioral stimulus; classically, it implied an innate or instinctual internal stimulus. *See also* drive; instinct; motivation.

needle phobia The persistent, intense, pathologic fear of receiving an injection.

negative reinforcement *See* reinforcement.

negative symptoms In schizophrenia: flat affect, alogia, abulia, and apathy.

negative transference *See* transference.

negativism Verbal or nonverbal opposition or resistance to outside suggestions and advice; commonly seen in schizophrenia in which the patient resists any effort to be moved or does the opposite of what is asked.

neologism New word or phrase whose derivation cannot be understood; often seen in schizophrenia. It has also been used to mean a word that has been incorrectly constructed but whose origins are nonetheless understandable (e.g., “headshoe” mean “hat”), but such constructions are more properly referred to as word approximations.

nervous breakdown Nonspecific lay term for mental disorder, often implying an acute decompensation.

neurasthenia Condition characterized by vague functional physical and mental fatigue; not used in DSM.

neurochemistry Branch of chemistry concerned with nervous system components, metabolism, and function.

neurocirculatory asthenia DA COSTA SYNDROME.

neuroendocrinology Subspecialty area concerned with the anatomical and functional relationships between the nervous system and the endocrine apparatus. *See also* psychoendocrinology.

neurohormone Chemical messengers formed by neurosecretory cells and released into the bloodstream.

neuroleptic drug ANTIPSYCHOTIC.

neuroleptic malignant syndrome (NMS) Life-threatening complication of antipsychotic treatment, including such symptoms as muscle rigidity and dystonia, akinesia, mutism, obtundation, and agitation.

neurologic amnesia **1.** Auditory amnesia: loss of ability to comprehend sounds or speech. *See also* Wernicke aphasia. **2.** Tactile amnesia: loss of ability to judge the shape of objects by touch. *See also* astereognosis. **3.** Verbal amnesia: loss of ability to remember words. **4.** Visual amnesia: loss of ability to recall or recognize familiar objects or printed words.

neurologic disorders Disorders involving the organization and function of nervous tissue, including diseases of the peripheral nerves, the spinal cord, and the brain, which are based on organic pathology.

neurologist Physician who specializes in diseases of the nervous system.

neurology Medical specialty concerned with organic diseases of the nervous system.

neuron Nerve cell, consisting of cell body, dendrites, and neuroaxon, which is the basic functional unit of the nervous system.

neuronal plasticity Ability of the central nervous system to alter its functional organization; a capacity for change that serves as a mechanism to shape neuronal circuitry during development, to change the way information is processed, and to compensate for injury.

neurophysiology Physiology of the nervous system.

neuropsychiatry Medical specialty that combines psychiatry and neurology.

neuroreceptors Neuronal and other nervous tissue sites that are stimulated or inhibited by neurotransmitters and/or psychotropic drugs.

neuroscience Branch of the life sciences concerned with the anatomy, physiology, biochemistry, or molecular biology of nerves and nervous tissue and, especially, with their relation to behavior and learning.

neurosis Mental or psychiatric disorder characterized primarily by anxiety, which may either be directly experienced and dominate the clinical picture or be unconsciously controlled and modified by various psychological mechanisms to produce other subjectively distressing and ego-alien symptoms. Although neuroses are not accompanied by gross distortion of reality or severe personality disorganization, normal functioning is impaired by the person’s symptoms; they have no organic basis, are relatively persistent, and are treatable. Also called psychoneurosis.

neurotic disorder *See* neurosis.

neurotic process Process in which unconscious conflict is expressed by neurotic symptoms or personality disturbance.

neurotoxin Agent, such as an antibody, causing destruction to nervous tissue.

neurotransmitter Any specific chemical agent released by a presynaptic cell that, upon excitation, crosses the synapse to stimulate or inhibit the postsynaptic cell.

NIAAA National Institute of Alcohol Abuse and Alcoholism.

nicotine dependence Inability to control the use of and dependence on tobacco. Nicotine dependence and withdrawal are classified as disorders in DSM.

NIDA National Institute of Drug Abuse.

night eating syndrome Eating disorder characterized by the consumption of large amounts of food after dinner; generally associated with insomnia and a lack of daytime appetite. In DSM-5, included in “Other Specified Feeding or Eating Disorders.”

night hospital Part-time hospital facility in which patients function in the outside world during the day but return to the hospital at night. *Compare* day hospital; weekend hospital.

nightmare Anxiety attack experienced while having terrifying or frightening dreams; characterized by mild anxiety, good recall of the dream, and mild autonomic reactions. *Compare* nightmare disorder; sleep terror disorder.

nightmare disorder Sleep disorder characterized by frequent nightmares and associated insomnia resulting from a fear of sleep.

night-terror SLEEP TERROR DISORDER.

nihilism Delusion of the nonexistence of the self or part of the self; also refers to an attitude of total rejection of established values or extreme skepticism regarding moral and value judgments.

nihilistic delusion Delusional disorder in which patients believe the world and everything related to it have ceased to exist.

NIMH National Institute of Mental Health.

nitrogen narcosis RAPTURE-OF-THE-DEEP SYNDROME.

NMS Neuroleptic malignant syndrome.

noesis Revelation in which immense illumination occurs in association with a sense that one has been chosen to lead and command. Can occur in manic or dissociative states.

nominal aphasia Aphasia characterized by difficulty in giving the correct name of an object. *See also* anomia; amnestic aphasia.

nonaffective hallucination Hallucination whose content is apparently unrelated to either depression or elation. *Compare* illusion.

noncomplementary role *See* role.

noncompliance with medical treatment DSM category used when a patient does not cooperate with the physician in their medical care; motivated by denial of illness, by religious beliefs, or by decisions based on personal value judgments about the advantages and disadvantages of the proposed treatment.

nondirective approach Technique in which the therapist follows the lead of the patient in the interview, rather than introducing their own theories and directing the course of the interview; applied in both individual and group therapy.

nonfluent aphasia MOTOR APHASIA.

nonparametric Denoting statistical methods that do not require restrictive assumptions about population distributions.

nonreactive depression ENDOGENOUS DEPRESSION.

nonsuicidal self-injury A DSM-5 disorder in which the patient intentionally inflicts damage to their body to induce bruises, bleeding, or pain without suicidal ideation. Also called self-mutilation.

non–24-hour sleep–wake circadian rhythm disorder A sleep–wake disorder characterized by a circadian period that is not congruent with the external environment; common in the blind, visually impaired, and those with traumatic brain injury.

noradrenaline NOREPINEPHRINE.

norepinephrine Catecholamine neurotransmitter substance liberated by adrenergic postganglionic neurons of the sympathetic nervous system; the precursor of epinephrine present in the adrenal medulla and also found in many areas of the brain. A disturbance in its metabolism at important brain sites has been proposed as an important factor in the causation of mood disorders. Also called noradrenaline.

normality In psychiatry, the absence of mental illness; that state of mental health about which there exists a scientific and professional consensus. The normal person has a sense of their own worth and maintains a confident and purposeful self-image.

nosology Science of the classification of diseases.

nosophobia PATHOPHOBIA.

not-for-profit hospital Any hospital not maintained for the purpose of monetary gain. *Compare* for-profit hospital.

not otherwise specified (NOS) Term used in previous editions of DSM to describe unusual or uncharacteristic variations of different mental disorders; for example, eating disorder NOS, tic disorder NOS, pervasive developmental disorder NOS.

NREM sleep Non-REM sleep consisting of four stages, based on EEG findings: stage 1: low amplitude, first frequency immediately after sleep begins; stage 2: cycles of 12 to 16 Hz called sleep spindles; stages 3 and 4: increased amplitude and slow frequency EEG changes. *Compare* REM sleep.

NTL National Training Laboratories.

nuclear family Immediate members of a family, including the parents and the children.

nuclear magnetic resonance (NMR) *See* magnetic resonance imaging.

null hypothesis Research term for the hypothetical assumption that any difference observed between two groups or conditions or between a particular group and the general population is purely accidental and due to chance alone. *See also* Type 1 error; Type 2 error.

nyctophobia Abnormal fear of darkness or of the night.

nymphomania Abnormal, excessive, insatiable desire in a female for sexual intercourse. *Compare* satyriasis.

O

objective tests Typically, pencil-and-paper tests based on specific items and questions and that yield numerical scores and profiles easily subjected to mathematical or statistical analysis; for example, Minnesota Multiphasic Personality Inventory (MMPI).

object permanence As described by Jean Piaget, the child's (birth to 2 years) ability to understand that objects have an existence independent of their involvement with the object; the child is able to maintain a mental image of a person or object even though it is not present and not visible.

object relation Emotional attachment formed between one person and another, as opposed to interest in and love for oneself.

OBS Organic brain syndrome.

OSA Obstructive sleep apnea syndrome.

obsession Persistent and recurrent idea, thought, or impulse that cannot be eliminated from consciousness by logic or reasoning; obsessions are involuntary and ego-dystonic. *See also* compulsion.

obsessional jealousy disorder Descriptive condition in which a person has persistent thoughts about infidelity in a partner or spouse; not a diagnosis in DSM-5.

obsessive-compulsive disorder (OCD) Neurotic disorder characterized by the persistent recurrence of obsessions and compulsions.

obsessive-compulsive personality Personality disorder characterized by perfectionism, overconscientiousness, and excessive inhibition with regard to self-expression and relaxation. Also called anancastic personality.

obstructive sleep apnea syndrome (OSA) A dyssomnia characterized by periods of functional obstruction of the upper airway during sleepy, resulting in degreases in oxygen, after which breathing (at least briefly) resumes normally.

occupational problem Maladaptive patterns related to work. For example, job dissatisfaction and uncertainties about career choices.

occupational psychiatry Area of psychiatry concerned with mental illness in industry, including the psychiatric aspects of absenteeism, vocational adjustment, operational fatigue, and accident proneness.

occupational therapy Form of therapy in which the patient engages in useful, purposeful activities in a therapeutic social setting involving interaction with other patients and hospital personnel.

OCD Obsessive-compulsive disorder.

oedipal phase PHALLIC PHASE. *See also* Oedipus complex.

Oedipus complex Constellation of feelings, impulses, and conflicts in the developing child that concern sexual impulses and attraction toward the opposite-sex parent and aggressive, hostile, or envious feelings toward the same-sex parent; real or fantasied threats from the same-sex parent result in the repression of those feelings. Development of the Oedipus complex coincides with the phallic phase of psychosexual development; as one of Freud's most important concepts, the term was originally applied only to the male. *Compare* Electra complex.

olfactory hallucination Hallucination primarily involving smell or odors; most common in medical disorders, especially in the temporal lobe.

Olfactory reference syndrome Alternate term for monosymptomatic hypochondriacal psychosis with delusions of foul body odor.

oligophrenia Old term for mental retardation.

OMD Organic mental disorder.

OMS Organic mental syndrome.

onanism Coitus interruptus. Sometimes used interchangeably with masturbation.

oneiroid state Dream-like state in which a patient is deeply perplexed and not fully oriented in time and place.

ontogenetic Pertaining to the development of an individual person. *Compare* phylogenetic.

open hospital Mental hospital without locked doors or physical restraints.

operant behavior *See* conditioning.

operant conditioning *See* conditioning.

operational definition Means of defining a word so that it is scientifically measurable.

opiate Morphine or other alkaloids derived from opium, an extractable product of the poppy plant *Papaver somniferum* or its variety, *P. album. See also* opioid.

opiate receptor Specific site on a neuronal cell surface that interacts with opiate drugs and mediates their pharmacologic actions; presumably, it also mediates the physiologic functions of endogenous opioids, such as the enkephalins and endorphins.

opioid Any chemical substance that has morphine-like pharmacologic activity; for example, narcotic analgesics, such as methadone and meperidine, and endogenous opioid peptides, the enkephalins and the endorphins. *See also* opiate.

opioid peptide Peptide that exerts morphine-like actions through interactions with opiate receptors; for example, endorphin, enkephalin.

oppositional defiant disorder Mental disorder of childhood characterized by pervasive negativism, continuous argumentativeness, and an unwillingness to comply with reasonable suggestions and persuasion.

oral dyskinesia *See* tardive dyskinesia.

oral phase Earliest stage in psychosexual development, which lasts through the first 18 months of life. During this period the oral zone is the center of the infant's needs, expression, and pleasurable erotic experiences; it has a strong influence on the organization and development of the child's psyche.

organic A term used in psychiatry to denote a structural change or a chemical imbalance in the brain to account for a mental disorder. The term is still in common use but is no longer part of the official DSM nomenclature. *See also* organic disorder.

organic anxiety syndrome Syndrome characterized by prominent, recurrent panic attacks or generalized anxiety attributable to some clearly defined organic factor; cognitive functioning may be adversely affected as a secondary phenomenon.

organic brain syndrome (OBS) ORGANIC MENTAL SYNDROME.

organic delusional disorder Disorder characterized by the presence of prominent delusions in a state of full wakefulness and alertness than can be attributed to some clearly defined organic factor.

organic disorder Illness that is caused by structural or biochemical pathology. The term is not used in DSM but remains in common use. *Compare* functional disorder.

organic hallucinosis Disorder characterized by prominent or persistent hallucinations in a state of full wakefulness that can be attributed to some specific organic factor.

organic mental disorder (OMD) Mental disorder caused by transient or permanent brain dysfunction attributable to specific organic factors. In DSM, the organic mental disorders include dementias arising in the senium and presenium, psychoactive substance-induced organic mental disorders, and organic disorders associated with Axis III physical disorders or conditions or whose etiology is unknown. Also called organic psychosis.

organic mental syndrome (OMS) Psychological or behavior abnormality associated with transient or permanent dysfunction of the brain of unknown or unspecified etiology. OMS is characterized by a combination of disorientation to time, place, or person; signs of psychosis, for example, hallucinations or delusions; and impaired judgment and impulse control. The organic mental syndromes include delirium, dementia, amnestic syndrome, organic delusional syndrome, organic hallucinosis, organic mood syndrome, organic anxiety syndrome, organic personality syndrome, intoxication, and withdrawal; if the cause is known, the condition is called organic mental disorder. Also called organic brain syndrome. Both terms are considered obsolete given their implied mind-brain dichotomy.

organic mood syndrome Obsolete disorder characterized by either a depressive or a manic mood attributed to a clearly organic factor.

organic personality syndrome Term for frontal lobe syndrome.

organic psychosis ORGANIC MENTAL DISORDER.

orgasm Sexual climax, the peak psychophysiologic reaction to sexual stimulation.

orgasm disorders One of the major categories of sexual dysfunctions. Characterized by the recurrent and persistent inability to achieve orgasm. Also called orgasmic dysfunction.

orgasmic phase Stage in the human sexual response cycle, as described by Masters and Johnson, in which orgasm occurs.

orgasmic platform Outer third of the vagina, which displays marked vasocongestion and contraction in the plateau phase of the female sexual response cycle, as described by Masters and Johnson.

orientation State of awareness of oneself and one's surroundings in terms of time, place, and person.

original thirteen *See* American Psychiatric Association.

orphan drug Any pharmacologic agent that is not economical to produce because the condition for which it is indicated affects relatively few persons.

Othello syndrome Eponym for conjugal paranoia.

orthomolecular psychiatry Theoretical school of thought proposing that psychiatric illnesses are due to biochemical abnormalities that result in increased requirements for specific substances, such as vitamins.

orthomolecular treatment Treatment that entails administration to psychiatric patients of large doses (megadoses) of vitamins (megavitamin therapy), trace elements, or other substances.

orthopsychiatry Interdisciplinary approach to the study and practice of maintaining or restoring mental health, involving principles derived from psychiatry, psychology, sociology, social work, medicine, and other fields; particular emphasis is placed on preventive techniques to promote healthy emotional development and growth, especially mental hygiene.

orthostatic hypotension Reduction in blood pressure brought about by a shift from a recumbent position to an upright position; observed as a side effect of several psychotropic drugs.

other-directed person Person who is readily influenced and guided by the attitudes and values of other people. *Compare* inner-directed person.

other interpersonal problems DSM category describing problems between one or more persons that cause sufficient strain to bring a person into contact with the mental health care system; the stress-inducing circumstances, coping mechanism, and symptoms that have brought someone to seek consultation or treatment must be individually evaluated.

other specified family circumstance DSM category used when the focus of attention or treatment is not due to a mental disorder or a parent–child or marital problem; may involve in-laws, grandparents, or other family members.

outcome variable DEPENDENT VARIABLE.

outpatient Ambulatory patient receiving medical care who does not require hospitalization.

ovarian dysgenesis TURNER SYNDROME.

overactivity Abnormality in motor behavior that can manifest itself as psychomotor agitation, hyperactivity (hyperkinesis), tics, sleepwalking, or compulsions.

overanxious disorder Anxiety disorder of childhood or adolescence characterized by excessive worrying and fearful behavior grossly disproportionate to the magnitude of the real environmental stress or threat.

overcompensation Conscious or unconscious exaggerated correction or compensation for a real or imagined physical or psychological deficit.

overdetermination Concept that phenomena such as dreams and neurotic symptoms reflect the operation of multiple causative factors, particularly with regard to symbolic meaning or significance.

overt homosexuality Behaviorally expressed homosexuality, as distinct from unexpressed conscious or unconscious homoerotic wishes that are held in check (latent homosexuality).

overvalued idea False or unreasonable belief or idea that is sustained beyond the bounds of reason. It is held with less intensity or duration than a delusion but is usually associated with mental illness.

P

pain disorder Disorder characterized by multiple, recurrent pain complaints with no apparent physical cause; symptoms are linked to psychological factors. Pain disorder is a variant of somatic symptom disorder in which pain symptoms are the predominant physical complaints. The field of pain medicine encompasses pain linked to both psychological and/or organic factors.

Pain–pleasure principle Psychoanalytic concept which states that, in psychic functioning, a person tends to seek pleasure and avoid pain. *See also* pleasure principle.

panic Acute, intense attack of anxiety associated with personality disorganization; the anxiety is overwhelming and accompanied by feelings of impending doom.

panic attack Episode of acute intense anxiety occurring in panic disorder, schizophrenia, major depression, and somatization disorder.

panic disorder DSM classification of anxiety disorder characterized by attacks of acute intense anxiety, with or without agoraphobia.

panphobia Overwhelming fear of everything.

pantomime Gesticulation; psychodrama without the use of words.

paradoxical sleep REM SLEEP.

paralogia EVASION.

paralysisagitans PARKINSONISM.

paralytic ileus Intestinal obstruction resulting from inhibition of bowel motility, a rare anticholinergic side effect of certain psychoactive drugs. Also called adynamic ileus.

parameter Way of measuring or describing an object or evaluating a subject.

parametric tests of significance Statistical methods used to estimate population parameters, such as the mean and standard deviation; use of these methods requires assumptions about the population characteristics, for example, that the variable under study is normally distributed within the population from which the sample is drawn.

paramnesia Disturbance of memory in which reality and fantasy are confused. It is observed in dreams and in certain types of schizophrenia and organic mental disorders; includes phenomena such as déjà vu and déjà entendu, which may occur occasionally in normal persons.

paranoia Rare psychiatric syndrome marked by the gradual development of a highly elaborate and complex delusional system, generally involving persecutory or grandiose delusions, with few other signs of personality disorganization or thought disorder.

paranoiac Person with paranoia.

paranoid delusion Includes persecutory delusions and delusions of reference, control, and grandeur.

paranoid disorder *See* delusional disorder.

paranoid ideation Thinking dominated by suspicious, persecutory, or grandiose content of less than delusional proportions.

paranoid personality disorder Personality disorder characterized by rigidity, hypersensitivity, unwarranted suspicion, jealousy, envy, an exaggerated sense of self-importance, and a tendency to blame and ascribe evil motives to others.

paranoid schizophrenia Type of schizophrenia characterized by the presence of persecutory or grandiose delusions, often accompanied by hallucinations; no longer included in DSM-5.

paraphasia Abnormal speech in which one word is substituted for another, the irrelevant word generally resembling the required one in its morphology, meaning, or phonetic composition; the inappropriate word may be either a legitimate one used incorrectly, such as “clover” instead of “hand,” or a bizarre nonsense expression, such as “treen” instead of “train.” Paraphasic speech may be seen in organic aphasias and in mental disorders, such as schizophrenia. *See also* metonymy; word approximation.

paraphilia Psychosexual disorder with a sexual dysfunction characterized by persistent and recurrent sexual fantasies, often of an unusual nature, without which imagery erotic arousal or orgasm is not attained; fantasies generally involve themes of suffering, humiliation, sexual activity with nonconsenting partners, or preference for a nonhuman object for sexual arousal. In DSM, the paraphilias include fetishistic disorder, transvestic disorder, frotteuristic disorder, pedophilic disorder, exhibitionistic disorder, voyeuristic disorder, sexual masochism disorder, and sexual sadism disorder. Also called sexual deviations.

paraphrenia Chronic condition characterized by fantastic and absurd delusions without significant personality deterioration and without the primary disturbances of thought and affect that characterize schizophrenia.

parapraxis Faulty act, such as a slip of the misplacement of an article. Freud ascribed parapraxes to unconscious motives.

paraprofessional Trained person who works in a mental hospital and may have a degree in the arts or from some professional school other than those serving the mental health group but has not obtained a degree in one of the usual mental health professions.

parapsychology Branch of psychology concerned with extranormal events and behavioral phenomena not accounted for or explained by the tenets and laws of contemporary science; for example, clairvoyance, telepathy, psychokinesis. *See also* metapsychology.

parasomnias A group of dysfunctions associated with sleep, sleep stages, or partial arousals characterized by unusual behavior, experiences, or physiologic events during sleep; composed of the three subtypes: non-REM movement sleep arousal disorders (incomplete awakening accompanied by sleepwalking, sleep-related eating, sleep-related sexual behavior, or sleep terror disorder); REM sleep behavior disorder (vocal or motor behavior during sleep); and nightmare disorder.

parasympathetic nervous system *See* autonomic nervous system.

parataxic distortion Harry Stack Sullivan’s term for distortions in judgment or attitude in interpersonal relations based on patterns set by earlier experience; previously developed ways of coping with significant people in a person’s life are applied by the person in later interpersonal integrations.

parens patriae Power of the state to involuntarily hospitalize mentally ill persons in need of care; also called “police power,” in that it prevents mentally ill persons from doing harm to themselves or to others.

Parent–child problem DSM category that refers to problems between a parent and a child; for example, in a family in which the parents are divorced, with either the custodial or the noncustodial parent, and in the remarriage of a divorced or widowed parent.

paresis Weakness or partial paralysis of organic origin.

paresthesia Abnormal spontaneous tactile sensation, such as a burning, tingling, or pins-and-needles sensation.

peripartum depression Depressed mood, anxiety, insomnia, and weight changes that occur near parturition or within 1 month of giving birth. Previously called postpartum depression.

parkinsonism Extrapyramidal dyskinesia characterized by resting tremor, rigidity, bradykinesia, and postural abnormalities. Parkinsonism is of unknown etiology and occurs in middle or late life, typically with a gradual progression and a prolonged course. Also called paralysis agitans; Parkinson disease; idiopathic parkinsonism. A parkinsonian syndrome may develop during the course of therapy with antipsychotic phenothiazine or butyrophenone drugs; such drug-induced parkinsonism is reversible when the causative drug is withdrawn or its dosage reduced.

Parkinson disease PARKINSONISM.

partial hospitalization System of treating mental illness in which the patient is hospitalized on a part-time basis. *See also* day hospital; night hospital; weekend hospital.

partial insanity MONOMANIA.

passive–aggressive personality disorder Personality disorder in which the patient manifests aggressive behavior in passive ways, such as obstructionism, pouting, stubbornness, and intentional inefficiency.

passive-dependent personality *See* dependent personality disorder.

pastoral counseling Use of psychotherapeutic principles by a clergyman in helping parishoners with emotional problems.

patch amnesia LOCALIZED AMNESIA.

pathognomonic Denoting a sign or symptom specifically diagnostic of a particular disease entity.

pathologic gambling Compulsion to gamble, one of the disorders of impulse control. *See also* gambling disorder.

pathologic intoxication ALCOHOL IDIOSYNCRATIC INTOXICATION.

pathophobia Abnormal fear of disease or suffering. Also called nosophobia.

paucity of speech Limited use of speech, seen in various pathologic states.

pavlovian conditioning CLASSICAL CONDITIONING. *See* conditioning.

Pavlov, Ivan Petrovich (1849–1936) Russian neurophysiologist famous for his work in conditioning.

pavor nocturnus SLEEP TERROR DISORDER.

PCP Phencyclidine.

peccatophobia Abnormal fear of sinning.

pecking order Hierarchy or sequence of authority in an organization or social group.

pederasty Anal intercourse between a man and a boy.

pedophilia Paraphilia in which a child is the sexual object.

pedophobia Abnormal fear of children.

peer review Review of physician services by a panel of other physicians.

Peer Review Organization (PRO) Federal review organization for hospitals receiving Medicare funds. In order to promote compliance with federal guidelines for health and hospital care, the PRO conducts independent utilization reviews and quality-of-care studies, validates diagnostic-related group (DRG) assignments, and reviews hospital admissions and readmissions. *See also* Professional Standards Review Organization; utilization review committee.

pellagra Deficiency of niacin (nicotinamide) characterized by diarrhea, dermatitis, and mental disturbance.

penis envy Sigmund Freud's concept that the woman envies the man for his possession of a penis; sometimes used to refer to a woman's generalized envy of men. A controversial concept given its heteronormative and patriarchal assumptions.

perception Conscious awareness of elements in the environment by the mental processing of sensory stimuli; sometimes used in a broader sense to refer to the mental process by which all kinds of data, intellectual, emotional, as well as sensory, are meaningfully organized. *See also* apperception.

perfectionism Practice of demanding of others or of oneself a higher quality of performance than is required by the situation.

period prevalence Research term for the total number of cases of a disease known to have existed during a specified time period. *Compare* point prevalence.

perseveration **1.** Pathologic repetition of the same response to different stimuli, as in a repetition of the same verbal response to different questions. **2.** Persistent repetition of specific words or concepts in the process of speaking. Seen in organic mental disorders, schizophrenia, and other mental illness. *See also* verbigeration.

persistence Term used to reflect a personality trait characterized by ambition, overachievement, resistance to frustration, and fatigue. Persistence may be enhanced by psychostimulants.

persistent (chronic) motor or vocal tic disorder A type of motor disorder consisting of either motor or vocal tics, but not both, that develops before adulthood. Compare Tourette disorder.

persistent complex bereavement disorder Disorder characterized by chronic and persistent grief about the death of someone close to the patient, accompanied by feelings of bitterness, anger, or ambivalence toward the deceased and social withdrawal. Also known as complicated grief or complicated bereavement.

persona In Jungian psychology, the outside personality that a person presents to the world, as opposed to their inner self (anima).

personality Characteristic configuration of behavior response patterns that each person evolves as a reflection of their individual adjustment to life.

personality disorder Mental disorder characterized by inflexible, deeply ingrained, maladaptive patterns of adjustment to life that cause either subjective distress or significant impairment of adaptive functioning; manifestations are generally recognizable in adolescence or earlier. Personality disorders listed in DSM include paranoid, schizoid, schizotypal, histrionic, narcissistic, antisocial, borderline, avoidant, dependent, and obsessive-compulsive.

personality traits Descriptive features of an individual's personality that are within normal limits.

persuasion Supportive psychotherapy in which the patient is encouraged to follow advice; persuasion is directive and limited in its goals.

pervasive developmental disorder Class of developmental disorders characterized by severe distortions in social skills, language, and contact with reality (e.g., autism spectrum disorder). Many psychological functions are deficient, and a child with this type of disorder displays abnormalities that are not normal for any stage of development. This condition was previously known as childhood schizophrenia. In DSM-5, Asperger syndrome, Rett syndrome, and childhood disintegrative disorder are types of pervasive developmental disorders. *Compare* specific learning disorder.

pervasive developmental disorder not otherwise specified A diagnostic category used in DSM-5 to refer to pervasive developmental disorders that may have contradictory features and/or lack sufficient findings to meet full criteria for one of the other pervasive developmental disorders (autism, Asperger syndrome, Rett syndrome, childhood disintegrative disorder).

perversion Deviation from the expected norm. In psychiatry it commonly signifies sexual perversion. *See also* psychosexual disorder.

perverted logic EVASION.

PET Positron emission tomography.

petit mal epilepsy Epileptic disorder characterized by recurrent minor, nonconvulsive, momentary lapses of consciousness, commonly beginning in childhood and having a self-limited course. A typical attack involves a sudden transient loss of contact with the environment, during which the patient develops a dazed expression and pauses in what he is doing; this type of seizure has a classical electroencephalographic representation consisting of synchronous, symmetrical spike-and-wave discharges at 3 per second, without cortical localization. Also called absence epilepsy; minor epilepsy.

phallic overbearance Domination of another person by aggressive means; generally associated with masculinity in its negative aspects.

phallic phase Third stage in psychosexual development, following the anal stage and lasting from about age 2 or 3 to about age 6; resolution of the Oedipus complex is the dominant developmental conflict during this stage. During this period, sexual interest, curiosity, and pleasurable experiences are centered on the penis in boys and the clitoris in girls. Also called oedipal phase.

phantasy Alternative spelling of fantasy.

phantom limb False sensation that an extremity that has been lost is in fact present.

pharmacokinetics Way in which the body processes a drug; its principal divisions are drug absorption, distribution, metabolism, and excretion.

pharmacotherapy PSYCHOPHARMACOLOGY.

phase of life problem DSM category that refers to problems not severe enough to warrant a psychiatric diagnosis but that interfere with functioning, as arising from marriage, work, change in job, culture shock.

phencyclidine (PCP) Substance of abuse with effects similar to hallucinogens. Also called angel dust.

phenomenology Study of events or happenings in their own right, rather than from the point of view of inferred causes; associated with existential psychiatry and reflects the theory that behavior is determined by the way the person perceives reality, rather than by external reality in objective terms.

phenothiazine One of a class of psychotropic drugs, the prototype of which is chlorpromazine, which are effective in the treatment of psychoses, especially schizophrenia; they exert a favorable influence with regard to the fundamental symptoms of schizophrenia as well as the secondary or accessory symptoms. Their mechanism of action may be related to the blockade of dopamine receptors at critical sites in the central nervous system.

phenotype Outward, observable expression of a person's genetic constitution. *Compare* genotype.

phenylketonuria (PKU) Genetic metabolic disorder characterized by the inability to convert the amino acid phenylalanine to tyrosine. If untreated, severe mental retardation results from the accumulation of large concentrations of toxic phenylketones; when detected early in infancy, the condition is treatable by the elimination of phenylalanine from the diet.

phenylpyruvic oligophrenia Former name for phenylketonuria.

pheromone Chemical signal that a person releases into the external environment and that affects the behavior or physiologic states of other persons.

phobia Persistent, pathologic, unrealistic, intense fear of an objector situation; the phobic person may realize that the fear is irrational but is, nonetheless, unable to dispel it. Some examples are: acarophobia (small objects), acrophobia (high places), agoraphobia (open places, leaving familiar setting of home), aichmophobia (pointed objects), ailurophobia (cats), algophobia (pain), androphobia (men), astraphobia or astrapophobia (thunder and lightning), autophobia (being alone, or of self), bathophobia (depths), claustrophobia (closed or confined places), coprophobia (excreta), cynophobia (dogs), demophobia (crowds), erythrophobia (blushing), gynophobia (women), haphephobia (being touched), hematophobia (sight of blood), hydrophobia (water), hypnophobia (sleep), lalophobia or glossophobia (speaking), mysophobia (dirt, contamination), necrophobia (dead bodies), nyctophobia (darkness, night), panphobia (everything), pathophobia or nosophobia (disease, suffering), peccatophobia (sinning), pedophobia (children), phonophobia (speaking aloud), photophobia (strong light), sitophobia (eating), taphophobia (being buried alive), thanatophobia (death), toxophobia (being poisoned), xenophobia (strangers), zoophobia (animals).

phobic disorder Frequent disorder characterized by a specific fear, which may represent a temptation, a punishment for the forbidden impulse, or a combination of both.

phobic neurosis PHOBIC DISORDER.

phonologic disorder *See* developmental articulation disorder.

phonophobia Abnormal fear of speaking aloud.

photophobia Abnormal fear of strong light.

phrenology Study of the bony conformation of the skull in the now discredited belief that it related to mental faculties and traits.

phylogenetic Pertaining to the development of the species. *Compare* ontogenetic.

physical dependence *See* drug dependence.

physical disorder Disorder of body function whose manifestations are not primarily behavioral or psychological.

Piaget, Jean (1896–1980) Swiss psychologist noted for his research on cognitive development in children; he divided the development of intelligence into three major periods: Sensorimotor (birth to 2 years), concrete operations (2 to 12 years), and formal operations (12 years through adult life).

piblokto Culture-specific syndrome seen in Eskimos, usually women, in which the affected person screams, cries, runs naked through the snow, sometimes with suicidal or homicidal tendencies.

pica Craving and eating of nonfood substances, such as paint and clay.

Pick disease *See* frontotemporal dementia.

pickwickian syndrome Condition characterized by obesity, hypoventilation, and hypersomnia.

Pinel, Phillipe (1746–1826) French reformer in the field of mental illness known for his work in abolishing physical restraints on hospitalized mental patients.

piperazine Phenothiazine derivative with antipsychotic affects; for example, fluphenazine (Prolixin).

piperidine Phenothiazine derivative with antipsychotic effects; for example, thioridazine (Mellaril).

PKU Phenylketonuria.

placebo 1. Inactive substance or preparation that is given as though it were a pharmacologically active medicine; primarily used in controlled studies to determine the efficacy of medicinal preparations; any beneficial or deleterious effects of the placebo may be ascribed to psychological factors. **2.** Any type of treatment that has no specific effects on the particular illness involved.

placebo effect Phenomenon in which a person exhibits a clinically significant response to a pill containing a therapeutically inert substance or a treatment without specific effect on the person's condition. Placebo effects are not limited to subjective reports; physiologic functions may be objectively influenced.

plaques In psychiatry, pathologic masses of axons, neurons, and dendrites with a central amyloid core; associated with Alzheimer disease.

plasma level *See* blood level.

plasticity *See* neuronal plasticity.

plateau phase Stage in the human sexual response cycle, as described by Masters and Johnson, characterized by increased genital blood flow and sense of sexual excitement; it precedes orgasm.

play therapy Type of therapy used with children in which they reveal their problems on a fantasy level with dolls, clay, and other toys; the therapist intervenes opportunely with helpful explanations about the patient's responses and behavior in language geared to the child's comprehension. *See also* activity group therapy.

pleasure principle In psychoanalysis, the principle by which the id seeks immediate tension reduction by either direct or fantasied gratification; developmentally, the pleasure principle antedates the reality principle. Also called the pleasure-pain principle. *See also* reality principle.

pleonexia Psychiatric disorder in which the patient has an excessive desire to acquire wealth or objects.

pluralism In psychiatry, the notion that multiple factors affect behavior.

PMDD Premenstrual dysphoric disorder.

point prevalence Research term for the total number of cases of a disease known to have existed at a given point in time. *Compare* period prevalence.

police power PARENS PATRIAE.

polygenic Involving the combined action or effects of several genes.

polymorphous perverse sexuality Psychoanalytic conceptualization of sexuality in the human infant, for whom sexual gratification can be achieved by homosexual, heterosexual, or inanimate stimulation of several body zones; all humans, therefore, have the potential to develop sexual perversions in adulthood, depending on how the sexual drives are channeled developmentally.

polyphagia Excessive eating. *See also* bulimia nervosa.

polysomnography Battery of tests that include an electroencephalogram, electrocardiogram, and electromyogram; often given with tests for penile tumescence, blood oxygen saturation, body movement, body temperature, galvanic skin response, and gastric acid. The tests are of assistance in a variety of conditions, such as insomnia, nocturnal myoclonus, sleep apnea, enuresis, somnambulism, seizure disorders, impotence, vascular headache, gastroesophageal reflux, and depression.

polysubstance dependence Disorder characterized by dependence on at least three categories of psychoactive substances.

polyuria Excessive excretion of urine.

population Research term for the entire collection of a set of objects.

porphyria Metabolic disorder characterized by excessive urinary excretion of porphyrins (pigments found in hemoglobin and certain cellular enzyme systems) or their precursors; mental symptoms are prominent in the form known as acute intermittent porphyria. Abdominal pain, constipation, and neuromuscular disturbances complete the clinical picture. Attacks may be precipitated by barbiturates.

positive reinforcement *See* reinforcement.

positive symptoms In schizophrenia: hallucinations, delusions, and thought disorder.

positive transference *See* transference.

positron emission tomography (PET) Imaging technique using short-lived positron-emitting elements of oxygen, carbon, and nitrogen used to label organic compounds (e.g., glucose, amino acids, and neurotransmitters), which are then introduced into the body by injection or inhalation; energy emitted is recorded by scintillation detectors and computer analyzed to construct and display images of transverse sections of tissues, such as the brain. Quantitative data can be assessed in specific areas for such functions as blood flow, oxygen or glucose metabolism, and other complex physiologic phenomena; alterations in metabolism associated with disease and the actions of medications can also be monitored in this way.

postpartum depression *See* peripartum depression.

postpartum psychosis A descriptive term for depressive or psychotic symptoms in women who have recently given birth; a subtype of bipolar disorder in DSM-5. Also called puerperal psychosis. *See also* peripartum depression.

posttraumatic stress disorder (PTSD) Anxiety disorder that occurs after and as a result of a major, disturbing, out of the ordinary event in a person’s life, such as war or rape. The prominent symptoms of this disorder include nightmares, flashbacks, withdrawal, and hypervigilance; may have a delayed onset. *See also* acute stress disorder.

posturing Strange, fixed, and bizarre bodily positions held by a patient for an extended time. *See also* catatonia.

potency Male ability to perform the sexual act; specifically, the capacity to achieve and maintain an erection during coitus.

poverty of content of speech Speech that is quantitatively adequate but qualitatively inadequate because it imparts minimal, vague, or repetitious information.

poverty of speech Restriction in the amount of speech used; replies may be monosyllabic. *See also* laconic speech.

PPO Preferred Provider Organization.

practice effect Research term referring to the improvement of performance in a task as a result of repeated trials.

Prader–Willi syndrome A developmental disability as a result of a small deletion involving chromosome 15. Symptoms include compulsive eating, obesity, intellectual disability, hypogonadism, small stature, hypotonia, and small hands and feet. Children also exhibit oppositional and defiant behavior.

preconscious One of three divisions of the psyche in Freud’s topographic theory of the mind (the others being the conscious and unconscious), including all mental contents that are not in immediate awareness but that can be consciously recalled with effort.

predictive value Proportion of true-positive or true-negative tests; indicates what percentage of test outcomes are expected to coincide with assigned diagnoses.

predictor variable Test or score used to assess or predict future performance.

Preferred Provider Organization (PPO) Alternative delivery organization that employs a prospective payment system in which a corporation or insurance company forms an agreement with a particular group of community hospitals and doctors to supply health services to PPO members at a previously determined lower rate; patients enrolled in a PPO select their physicians and hospitals from among the list of participants.

prefrontal lobotomy *See* lobotomy.

pregenital stages In psychoanalysis, the first stages of psychosexual development (the oral and anal stages) that occur before the genitals have begun to exert the predominant influence on sexual behavior.

prejudice Preconceived adverse judgment or opinion formed without just grounds or sufficient knowledge; elements of irrational suspicion or hatred are often involved, as in racial prejudice.

premature ejaculation Ejaculation occurring before or immediately after vaginal intromission during coitus; broader definitions take into consideration the ability of a male to delay ejaculation during coitus for a sufficient length of time to satisfy a normally responsive female partner.

premenstrual dysphoric disorder (PMDD) Depressive mood disorder characterized by irritability, emotional lability, headache, and anxiety or depression that occurs about 1 week before menses and resolves after the menstrual cycle is complete. Also called late luteal phase dysphoric disorder.

premorbid Occurring before the onset of disease.

preoccupation of thought Centering of thought content on a particular idea, associated with a strong affective tone, such as paranoid trend or a suicidal or homicidal preoccupation.

presenile dementia DEMENTIA OF THE ALZHEIMER TYPE; PRESENILE ONSET.

presenium Period preceding old age, generally ages 55 to 65.

pressure of speech, pressured speech Increase in the amount of spontaneous speech; rapid, loud, accelerated speech, as occurs in mania, schizophrenia, and cognitive disorders.

prevalence Total number of cases of a disease existing at a given point in time (point prevalence) or during a specified time period (period prevalence). *See also* incidence.

prevalence rate Number of diagnosed cases of a disease or a condition at a particular point in time; prevalence rate per 1,000 is defined as the cases at a specific point in time, divided by the number of persons in the population at a specific point in time, multiplied by 1,000.

preventive psychiatry Branch of preventive medicine concerned with mental disorders. Encompassed within its scope are measures to prevent mental disorders (primary prevention); measures to limit the severity of illness, as through early case finding and treatment (secondary prevention); and measures to reduce disability after a disorder (tertiary prevention).

primal father Hypothetical head of a tribe depicted by Sigmund Freud in *Totem and Taboo* as slain by his sons, who subsequently devour him in a cannibalistic rite; later, he is promoted to a god. The son who murders him is the prototype of the tragic hero, and the memory of the crime is perpetuated in the conscience of the individual and of the culture.

primal scene In psychoanalysis, the real or fantasied observation by a child of sexual intercourse, particularly between their parents.

primary care physician Physician who specializes in family medicine, internal medicine, pediatrics, and obstetrics and gynecology; many believe psychiatry should be designated a primary care specialty.

primary diagnosis Major emotional disorder for which the patient is treated. Also called principal diagnosis.

primary gain Reduction of anxiety achieved by a defense mechanism; relief from tension or conflict through neurotic illness. *Compare* secondary gain.

primary narcissism *See* narcissism.

primary parkinsonism *See* parkinsonism.

primary prevention *See* preventive psychiatry.

primary process thinking In psychoanalysis, the mental activity directly related to the functions of the id and characteristic of unconscious mental processes; marked by primitive, prelogic thinking and by the tendency to seek immediate discharge and gratification of instinctual demands. Includes thinking that is dereistic, illogic, and magical; normally found in dreams, abnormally in psychosis. *Compare* secondary process thinking.

primary reinforcer *See* reinforcement.

primary retarded ejaculation Lifelong inability to ejaculate during coitus. *Compare* secondary ejaculation.

primitive idealization Defense mechanism in which external objects that are viewed as either “all good” or “all bad” are unrealistically endowed with great power; most commonly, the “all good” object is seen as omnipotent, or ideal, while the badness of the "all bad" object is greatly inflated.

Prince, Morton (1854–1929) American neurologist and psychiatrist known for his study of multiple personalities.

principal diagnosis PRIMARY DIAGNOSIS.

prion disease A class of disorders caused by a transmissible infectious protein. Includes Creutzfeldt–Jakob disease (CJD), Gerstmann–Straussler–Scheinker disorder, kuru, and fatal familial insomnia.

prison neurosis *See* chronophobia.

prison psychosis Psychotic reaction to incarceration or to the prospect of incarceration.

privacy 1. Limiting access of others to one's body or mind, including dreams, fantasies, thoughts, or beliefs. **2.** Freedom from intrusion by the state or third persons. **3.** Restricted areas of personal decision, usually in such matters as personal association, abortion, or bodily integrity.

privilege Legal term referring to the legal right of patients to prevent their physicians from testifying about information obtained in the course of treatment; the legal formulation of the ethical principle of confidentiality. In some states, information obtained in the course of the doctor–patient relationship is considered privileged communication.

privileged communication *See* privilege.

PRO Peer Review Organization.

probability Quantitative statement of the likelihood that an event will occur. A probability of 0 means that the event is certain not to occur; a probability of 1.0 means the event will occur with certainty.

problem-oriented record Method for organizing a patient's clinical chart, consisting of five parts: data base, problem list, treatment plan, progress notes, and discharge summary.

problem-solving Capacity of a person to master a new or novel task.

process schizophrenia Unofficial term for schizophrenia attributed more to endogenous factors than to specific environmental influences. *Compare* reactive schizophrenia.

prodrome Early symptom of a disease, often serving as a warning or premonitory sign of the approach of a morbid condition; for example, the aura preceding an epileptic seizure or classic migraine.

Professional Standards Review Organization (PSRO) Organization of physicians in a given region established to review the quality of health care services, particularly with regard to whether the inpatient services rendered are medically necessary. Such an organization has been required by federal law since 1972 in relation to hospital care under Medicare and Medicaid. *See also* peer review organization; utilization review committee.

profound mental retardation *See* mental retardation.

prognosis 1. Opinion as to the probable future course, extent, and outcome of an illness. **2.** Specific goals of therapy.

projection Unconscious defense mechanism in which a person attributes to another those generally unconscious ideas, thoughts, feelings, and impulses that are in themself undesirable or unacceptable as a form of protection from anxiety arising from an inner conflict; by externalizing whatever is unacceptable, the person deals with it as a situation apart from themselves. *See also* blind spot.

projective identification Defense mechanism in which unwanted aspects of the self are projected onto another person such that the individual projecting feels at one with the object of the projection. It allows one to distance and make oneself understood by exerting pressure on another individual to experience feelings similar to one’s own.

projective test Psychological test with loosely structured test material that requires the subject to reveal their own feelings, personality, or psychopathology; for example, Rorschach Test, Thematic Apperception Test.

prolactin Anterior pituitary hormone that has been studied as a potential index of dopamine activity and receptor sensitivity in studies of central nervous system function in psychiatric patients.

proprioception KINESTHETIC SENSE.

prosopagnosia Inability to recognize familiar faces that is not due to impaired visual acuity or level of consciousness.

prospective study Study based on observing events as they occur.

prototaxic Harry Stack Sullivan's term for primitive processes. *See also* primary process.

pseudoaggression Neurotic defense in which h patient denies basic masochistic feelings and displays them, instead, as false aggression.

pseudoauthenticity False or copied expression of thoughts and feelings.

pseudocollusion Sense of closeness, relationship, or cooperation that is not real but is based on transference.

pseudocyesis Rare condition in which a nonpregnant patient has the signs and symptoms of pregnancy, such as abdominal distention, breast enlargement, pigmentation, cessation of menses, and morning sickness.

pseudodementia 1. Dementia-like disorder that can be reversed by appropriate treatment and is not caused by organic brain disease. The current preferred term is Depressive Cognitive Disorder. **2.** Condition in which a patient shows an exaggerated indifference to their surroundings in the absence of a mental disorder; also occurs in depression and factitious disorders.

pseudologia fantastica Disorder characterized by uncontrollable lying in which a patient elaborates extensive fantasies that he freely communicates.

pseudomotor agitation Physical and mental overactivity that is usually nonproductive and is associated with a feeling of inner turmoil, as seen in agitated depression.

pseudoparkinsonism Syndrome that resembles Parkinson disease, resulting from long-term use of antipsychotic drugs. Also called drug-induced parkinsonism.

psilocin *See* psilocybin.

psilocybin 4-Phosphoryloxy-*N*′,*N*′-dimethyltryptamine, the active ingredient of various Mexican hallucinogenic mushrooms, which acts as a psychedelic drug producing changes in perception and mood and alterations of consciousness. A variation is called psilocin.

PSRO Professional Standards Review Organization.

psychalgia PSYCHOGENIC PAIN DISORDER.

psychasthenia Obsolete term used by Pierre Janet to describe a syndrome characterized by fears and phobias.

psyche Mind, as divided into conscious, preconscious, and unconscious in Sigmund Freud’s topographic model.

psychedelic Denoting drugs that may induce hallucinations and psychotic states. LSD is the prototype; other psychedelic drugs include mescaline, psilocybin, and marijuana.

psychiatric emergency Disturbance in thoughts, feelings, or actions for which immediate treatment is necessary; for example, suicide intent.

psychiatric illness *See* mental disorder.

psychiatric nurse Clinical nurse specialist who functions as part of the mental health team, usually in an institutional setting; often carries out individual, family, and group psychotherapy.

psychiatric social worker Skilled professional, trained in social work, who works with psychiatrists, usually in an institutional setting; evaluates family, environmental, and social factors in the patient’s illness; may work in intake and reception with new patients; may follow-up and counsel after discharge, and also carry out individual, family, and group psychotherapy and participate in community organizations.

psychiatrist Medical doctor whose specialty is the study and treatment of mental disorders. After receiving the M.D. degree, a physician spends 4 years as a resident in a hospital setting. When they pass the written and oral examinations of the American Board of Psychiatry and Neurology, they become a diplomat in psychiatry and is said to be Board certified.

psychiatry Branch of medicine concerned with the prevention, cause, and treatment of mental disorders.

psychic determinism Freudian concept that all mental phenomena have specific antecedent causes, often operating on an unconscious level.

psychic energizer Rarely used term for any antidepressant or stimulant drug.

psychic helplessness *See* helplessness.

psychic trauma Psychologically upsetting event that may have lasting consequences on a person's thinking, feeling, or behavior.

psychoactive drug PSYCHOTHERAPEUTIC DRUG.

psychoactive substance abuse *See* substance use disorder.

psychoactive substance dependence DSM term for drug dependence.

psychoactive substance-induced mental disorder Mental disorder caused by the direct effects on the nervous system of a drug or other substance. In DSM, the substances listed are alcohol; sedatives, hypnotics, or anxiolytics; inhalants; opioids; cocaine; amphetamine or similarly acting sympathomimetics; phencyclidine (PCP) or similarly acting arylcyclohexylamine; hallucinogens; cannabis; nicotine; and caffeine.

psychoanalysis Theory of human mental phenomena and behavior, a method of psychic investigation and research, and a form of psychotherapy originally formulated by Sigmund Freud. As a technique for exploring the mental processes, psychoanalysts includes the use of free association and the analysis and interpretation of dreams, resistances, and transferences. As a form of psychotherapy, it uses the investigative technique, guided by Freud's libido and instinct theories and by ego psychology, to gain insight into a person's unconscious motivations, conflicts, and symbols and thus to effect a change in maladaptive behavior. Also called analysis in depth.

psychoanalyst Psychotherapist, usually a psychiatrist, who has had training in psychoanalysis and who uses its techniques in a treatment setting.

psychoanalytic group psychotherapy Method of group psychotherapy pioneered by Alexander Wolf and based on the operational principles of individual psychoanalytic therapy; analysis and interpretation of a patient's transferences, resistances, and defenses are modified to take place in a group setting.

psychobiology Adolf Meyer's term referring to the study of the human being as an integrated unit, incorporating psychological, social, and biologic functions.

psychodrama Psychotherapy method originated by Jacob Moreno in which personality makeup, interpersonal relationships, conflicts, and emotional problems are expressed and explored through dramatization. Therapeutic dramatization of emotional problems includes: (1) protagonist or patient, the person who presents and acts out their emotional problems with the help of (2) auxiliary egos, persons trained to act and dramatize the different aspects of the patient that are called for in a particular scene in order to help the patient express feelings, and (3) the director, leader, or therapist, who guides those involved in the drama for a fruitful and therapeutic session.

psychodynamics Science of mental forces and motivations that influence human behavior and mental activity; the role of unconscious motivation in the causation of human behavior is

psychoendocrinology Study of the role of hormones on thinking, behavior, and emotional disorder.

Psychose passionelle *See* erotomania.

psychogenic Produced or caused by mental factors, rather than organic factors; usually refers to a symptom or an illness.

psychogenic amnesia Dissociative disorder characterized by the sudden inability to recall information stored in memory in the absence of an underlying organic mental disorder; in DSM listed as dissociative amnesia.

psychogenic fugue Dissociative disorder characterized by periods of total amnesia in which one travels and assumes a new identity. In DSM listed as Dissociative amnesia, with dissociative fugue. *See also* fugue; psychogenic amnesia.

psychogenic pain disorder Condition in which there is a preoccupation with pain for at least 6 months in the absence of organic pathology to account for the pain. Also called psychalgia; somatoform pain disorder in previous versions of DSM.

psychohistory Approach to history that examines events within a psychological framework; attempts to connect individual and collective ideas and emotions with wider historical currents.

psychoimmunology Study of the relationship between the immune system and emotions.

psychokinesis Parapsychological phenomenon in which directed thought processes influence physical events.

psycholinguistics Exploration of the psychological factors involved in the development and use of language.

psychological defense system *See* defense mechanism.

psychological factor affecting physical condition Disorder characterized by physical symptoms partially caused or affected by psychological factors; physiologic and organic changes stem in part from a sustained emotional disturbance; for example, atopic dermatitis, migraine, ulcer. Also called psychophysiologic disorder; psychosomatic disorder.

psychologist Person trained in psychology, usually with a graduate degree (M.A., Ph.D.).

psychology Study and profession concerned with mental processes and behavior.

psychometry Science of testing and measuring mental and psychological functioning.

psychomotor Relating to combined physical and mental activity.

psychomotor agitation Physical and mental overactivity associated with a feeling of inner turmoil, as seen in agitated depression.

psychomotor epilepsy COMPLEX PARTIAL SEIZURE.

psychomotor retardation Slowing of mental and physical activity, common in depression.

psychomotor stimulant Drug that arouses the patient through its central excitatory properties; for example, amphetamine, methylphenidate (Ritalin). Also called analeptic.

psychoneuroimmunology Study of psychological factors as causes of diseases or their effect on the course of disease, particularly as it relates to the immune system. *See also* psychoimmunology.

psychoneurosis NEUROSIS.

psycho-oncology Study of the role of emotions and their relation to cancer in terms of prevention, diagnosis, and treatment.

psychopathic personality Former term for the personality characteristic of antisocial personality disorder.

psychopathologic Denoting abnormal, maladaptive behavioral or mental activity.

psychopathology **1.** Study of mental disorders. **2.** Abnormal, maladaptive behavioral or mental activity.

psychopharmacology Study of the mental and behavioral effects of drugs. *See also* pharmacokinetics.

psychophysiologic disorder PSYCHOLOGICAL FACTOR AFFECTING PHYSICAL CONDITION.

psychopolitics **1.** Psychological dimensions of political behavior, such as the reciprocal influence on persons of political environments and their societies. **2.** Specific tactics of politicians that are intended to yield benefits to them through the use of psychological strategies.

psychosexual development **1.** Broadly, the maturation and development of the sexuality of a person throughout the life cycle. **2.** More specifically, in psychoanalysis, series of dynamic and crucial developmental stages that each person passes through and that influence basic personality characteristics in later life; the stages or phases are oral, anal, phallic, latency, and genital.

psychosexual disorder Disorder of sexual functioning, desire, or performance that is caused, wholly or partly, by psychological factors.

psychosis Mental disorder in which a person’s thoughts, affective response, ability to recognize reality, and ability to communicate and relate to others are sufficiently impaired to grossly interfere with their capacity to deal with reality; the classical characteristics of psychosis are impaired reality testing, hallucinations, delusions, and illusions.

psychosocial deprivation Deprivation of social and intellectual stimulation; believed to be a causative factor in mental retardation and emotional disorders in children.

psychosocial development Developmental progress of a person with regard to social relations and social reality, as primarily described by Erik Erikson. Specific developmental tasks characterize successive chronologic periods from infancy through maturity: trust versus mistrust (infancy), autonomy versus doubt (toddler), initiative versus guilt (preschool), industry versus inferiority (school age), identity versus identity diffusion (adolescence), intimacy versus isolation (young adulthood), generativity versus self-absorption (adulthood), and integrity versus despair (mature age).

psychosocial dwarfism Syndrome usually first manifested in children 2 to 3 years of age, who typically are unusually short, have frequent growth hormone abnormalities, and have severe behavioral disturbances; all of these symptoms are the result of an inimical caretaker–child relationship and resolve without any medical or psychiatric treatment upon being placed in a more favorable domicile. Also called psychosocially determined short stature.

psychosocially determined short stature PSYCHOSOCIAL DWARFISM.

psychosocial stressor STRESS.

psychosomatic disorder PSYCHOLOGICAL FACTOR AFFECTING PHYSICAL CONDITION.

psychosurgery Neurosurgical intervention to treat a mental disorder that involves destruction or ablation of brain tissue.

psychotherapeutic drug Drug used to alter abnormal thinking, feelings, or behavior; traditionally divided into classes of antipsychotic, antidepressant, antimanic, and antianxiety (anxiolytic) drugs. Also called psychoactive drug; psychotropic drug.

psychotherapist Person trained to treat mental, emotional, and behavioral disorders. For types of therapists, see the specific term.

psychotherapy Treatment for mental illness and behavioral disturbances in which a trained person establishes a professional contract with the patient and through definite therapeutic communication, both verbal and nonverbal, attempts to alleviate the emotional disturbance, reverse or change maladaptive patterns of behavior, and encourage personality growth and development; distinguished from other forms of psychiatric treatment such as the somatic therapies, for example, drug and convulsive therapies.

psychotic 1. Person suffering from a psychosis. **2.** Denoting or characteristic of a psychosis.

psychotic depressive reaction Psychosis distinguished by depressed mood precipitated by some event, usually in a person who had not previously demonstrated severe depression. Also called major depressive disorder, single episode, with mood-congruent psychotic features, in DSM.

psychotomimetic drug Drug that produces psychic and behavioral changes that resemble psychosis; unlike other drugs that can produce organic psychosis as a toxic reaction (e.g., hallucinogenic and psychedelic drugs such as LSD, marijuana, mescaline), a psychotomimetic drug does not produce gross confusion, delirium, or overt memory impairment.

psychotropic drug PSYCHOTHERAPEUTIC DRUG.

PTSD Posttraumatic stress disorder.

puerperal psychosis *See* postpartum psychosis.

punishment Presentation of an aversive stimulus contingent on an operant response, resulting in a decreased probability of that response recurring. *See also* reinforcement.

Purging disorder Eating disorder characterized by recurrent episodes of self-induced vomiting, laxative and diuretic abuse, and/or the use of enemas after consuming small amounts of food; patients are normal weight and have distorted body image. In DSM-5, included in “Other Specified Feeding or Eating Disorders.”

pyromania Compulsion to set fires.

Q

q-sort Technique of personality assessment based on the degree to which a standard set of descriptive statements are believed to describe a particular person.

quadrangular therapy Marital therapy that involves four people, the married pair and each spouse's therapist.

quality assurance Measurement and evaluation of medical and other related services provided with regard to their effectiveness, efficiency, appropriateness, and acceptability; such evaluation will trigger corrective or remedial action for services not meeting the desired standards.

quantitative variable Experimental factor that can be measured.

R

random Statistical term that means occurring by chance or without attention to selection or planning.

random sample In a given population, a group of subjects selected in such a manner that each member of the population has an equal probability of being selected for the sample.

random variable Variable for which the variation is determined by chance.

range Statistical measure of the variability of a set of values, defined as the difference between the largest value and the smallest value.

Rank, Otto (1884–1939) Austrian psychoanalyst, long-time secretary and recorder of the minutes of the Vienna Psychoanalytic Society, and one of Sigmund Freud's earliest followers, who split with him on the significance of the birth trauma, which Rank used as a basis of brief psychotherapy. Rank's works include *The Trauma of Birth* and *The Myth of the Birth of the Hero.*

rape Sexual intercourse without the person's consent and against their will, chiefly by force; usually heterosexual but may be homosexual.

rapid eye movement *See* REM latency; REM sleep.

rapport Conscious feeling of harmonious accord, sympathy, and mutual responsiveness between two or more persons; contributes to an effective therapeutic process in both group and individual settings.

rapture-of-the-deep syndrome Psychosis, seen in scuba and deep-sea divers, characterized by disorientation and loss of judgment and skill, and associated with excessive blood nitrogen levels; sensory deprivation may also contribute to this acute, self-limited mental disorder. Also called nitrogen narcosis.

rationalization Ernest Jones's term for an unconscious defense mechanism in which irrational or unacceptable behavior, motives, or feelings are logically justified or made consciously tolerable by plausible means.

Ray, Isaac (1807–1881) One of the original 13 founders of the American Psychiatric Association, known for his *Treatise on Medical Jurisprudence of Insanity* (1837).

rCBF Regional cerebral blood flow.

reaction formation Unconscious defense mechanism in which a person develops a socialized attitude or interest that is the direct antithesis of some infantile wish or impulse that is harbored either consciously or unconsciously. One of the earliest and most unstable defense mechanisms, closely related to repression; both are defenses against impulses or urges that are unacceptable to the ego.

reactive attachment disorder of infancy or early childhood Severe impairment of the ability to relate, beginning before age 5; presumed to develop from grossly pathologic care-giving.

reactive depression Mental disorder characterized by depression developing in reaction to some precipitating life event or circumstance.

reactive disorder Mental disorder judged to be a reaction to one or more life events or circumstances, without which the disorder would not have occurred. *See also* brief reactive psychosis; reactive depression; reactive schizophrenia.

reactive schizophrenia Unofficial term for schizophrenia attributed primarily to predisposing or precipitating environmental factors. *Compare* process schizophrenia.

reading disorder Reading below the expected level for a child's age, education, and intelligence.

reality Totality of objective things and factual events; includes everything that is perceived by a person's special senses and is validated by other people.

reality principle In psychoanalysis, ego processes that modify the demands of the pleasure principle to meet the inescapable demands and requirements of the outside world; net result is behavior that gratifies id impulses within realistic limits. *See also* pleasure principle.

reality testing Fundamental ego function that consists of tentative actions that test and objectively evaluate the nature and the limits of the environment; includes the ability to differentiate between the external world and the internal world and to accurately judge the relation between the self and the environment.

recall Process of bringing stored memories into consciousness. *See* memory.

receiver operating characteristic (ROC) Special statistical method, recently used in psychiatry, which gives a balance between sensitivity and specificity for a diagnostic test, for example, Dexamethasone Suppression Test. The method was derived from signal detection theory as a way to determine how well an electronic receiver was able to distinguish signal from noise.

recent memory Recall of events over the past few days.

recent past memory Recall of events over the past few months.

receptive aphasia Organic loss of ability to comprehend the meaning of words; fluid and spontaneous, but incoherent and nonsensical, speech. *See also* fluent aphasia and sensory aphasia.

receptive dysphasia Difficulty in comprehending oral language; the impairment involves both comprehension and production of language.

receptors Proteins in the neuronal membrane that are exposed in part to the extracellular fluid and specifically recognize neuromessengers; stimulation of receptors generally causes a biologic response to occur.

reciprocal inhibition and desensitization Behavior therapy in which a person is conditioned to associate comfortable, supportive surroundings with anxiety-producing stimuli, thus decreasing the anxiety associated with those stimuli.

recovered memory syndrome Condition that occurs when a repressed memory of a traumatic experience is brought back to consciousness, usually during psychotherapy or under hypnosis. A variant of this condition, false memory syndrome, occurs if the recalled memory did not actually happen, but the person believes the memory to be true.

recurrent brief depressive disorder Multiple, brief (less than 2 weeks duration) episodes of depressive symptoms.

recurrent depressive episode Depression that lasts between 2 and 13 days and occurs at least once a month.

recurrent isolated sleep paralysis Sleep disorder characterized by the inability to make voluntary movements while partially conscious at sleep onset or awakening. *See also* parasomnias.

refractory period Temporary state of psychophysiologic resistance to sexual stimulation immediately after orgasm in the human sexual response cycle, as described by Masters and Johnson.

reframing Technique used in family therapy whereby a problem or conflict is viewed by the therapist in an entirely different and sometimes startling perspective, thus enabling the family members to achieve objectivity.

regional cerebral blood flow (rCBF) Test using xenon-133, a low-energy gamma ray-emitting isotope, to determine blood flow in the brain; useful for studying diseases that have a decrease in the amount of brain tissue, for example, dementia, ischemia, atrophy.

registration *See* memory.

regression Unconscious defense mechanism in which a person undergoes a partial or total return to earlier patterns of adaptation;

observed in many psychiatric conditions, particularly schizophrenia.

regressive-reconstructive approach Psychotherapeutic procedure in which regression is made an integral element of the treatment process; an original traumatic situation is reproduced to gain new insight and to effect personality change and emotional maturation.

rehabilitation All methods and techniques used in an attempt to achieve maximal function and optimal adjustment in a given patient; the physical, mental, social, and vocational preparation of a patient for the fullest possible life compatible with their abilities and disabilities. Inasmuch as the process aims also to prevent relapses or recurrences of the patient's condition, it is sometimes called tertiary prevention.

Reich, Wilhelm (1897–1957) Austrian psychoanalyst who emigrated to the United States in 1939. He coined the term "orgone," a kind of universally pervasive physical and biologic energy that was typified by the pent-up libidinal energy that sought free expression and release through orgasm.

Reik, Theodor (1888–1969) Psychoanalyst and early follower of Sigmund Freud, who considered Reik one of his most brilliant pupils; Freud's book, *The Question of Lay Analysis*, was written to defend Reik's ability to practice psychoanalysis without medical training. Reik made many valuable contributions to psychoanalysis on the subjects of religion, masochism, and therapeutic technique.

reinforcement *Positive reinforcement* refers to the process by which certain consequences of behavior increase the probability that the behavior will occur again. Positive reinforcers tend to be viewed as pleasant. *Negative reinforcement* describes the process by which behavior that leads to the removal of an unpleasant event strengthens that behavior. Negative reinforcers tend to be viewed as unpleasant. Stimuli that possess inherent reinforcing characteristics are called *primary reinforcers*, for example, food. Stimuli that acquire reinforcing characteristics by being paired with primary reinforcers are called *conditioned reinforcers*, for example, money. *See also* conditioning.

reinforcer Reinforcing stimulus. *See* reinforcement.

relatedness Sense of sympathy and empathy with regard to others; sense of oneness with others. *Compare* isolation; alienation.

relational problems Impaired functioning of a relational unit. In DSM, parent–child relational problem, partner relational problem, and sibling relational problem.

relative frequency *See* frequency.

relative risk Epidemiologic measure of the risk of developing a disorder in a specified subset of the population as compared with the total population or a different subset of it. Comparison is usually made between groups exposed and groups not exposed to a particular hereditary or environmental factor to gain information about the role of that factor in the disorder in question. Relative risk is then expressed as a ratio of the frequency of the disorder in exposed persons to its frequency in those not exposed.

Relative Value Scale Payment scale for medical services developed at Harvard University that reimburses physicians in terms of time spent with patients, office overhead expenses, years of training, and cognitive skills; under the program, surgeons would receive less money and internists would receive more money from third-party (insurance) carriers than under previous payment scale programs. Also called Resource-Based Relative Value Scale (RBRVS).

reliability Research term meaning replicability, that is, the degree to which a test result or experimental finding can be confirmed by repetition. *See also* validity.

religious delusion Delusion involving the Deity or theologic themes.

reminiscence Recall or recollection of past experiences, with alternations of remembering an apparently lost memory and forgetting one that was just there.

remission Significant improvement or recovery which may or may not be permanent. *Compare* intermission.

remote memory LONG-TERM MEMORY.

remotivation Group treatment technique used patients in mental hospitals to encourage them and vocational skills.

REM (rapid eye movement) latency First REM episode of the night, about 90 minutes after sleep onset; shortening of REM latency frequency occurs with disorders such as depression and narcolepsy.

REM (rapid eye movement) sleep Stage of sleep during which dreaming occurs and the sleeper exhibits coordinated rapid eye movement (REM). The electroencephalogram demonstrates a desynchronized pattern of cerebral activity. It accounts for one-fourth to one-fifth of total sleep time. Also called paradoxical sleep.

REM sleep behavior disorder Sleep disorder characterized by the absence of sleep paralysis (atonia) during the REM stage of sleep; consequently, patients will act out their dreams, putting themselves and/or their partners at risk of physical injury. *See also* parasomnias.

repetition compulsion Psychoanalytic concept of an impulse to repeat earlier experiences and situations.

repetitive pattern Continual attitude or mode of behavior characteristic of a person and performed mechanically or unconsciously.

repression Freud’s term for an unconscious defense mechanism in which unacceptable mental contents are banished or kept out of consciousness; important in both normal psychological development and in neurotic and psychotic symptom formation. Freud recognized two kinds of repression: (1) repression proper, in which the repressed material was once in the conscious domain; (2) primal repression, in which the repressed material was never in the conscious realm. *Compare* suppression.

repressive-inspirational group psychotherapy Group therapy in which discussion is intended to bolster the patients’ morale and help them avoid undesired feelings; used primarily with large groups of seriously regressed patients in institutional settings.

reserpine Alkaloid extracted from the *Rauwolfia serpentina* plant, formerly used as an antipsychotic agent because of its sedative effects but currently used primarily as an antihypertensive agent, although this use has declined partly because of its potential to produce a considerable incidence of nightmares and suicidal depression; that untoward effect may be related to reserpine's depletion of catecholamines at critical sites in the central nervous system.

resident **1.** In psychiatry, a patient living in a treatment center for a prescribed period of time. **2.** In medicine, a physician in postgraduate training after graduation from medical school; 4 years of residency training are necessary to become a psychiatrist.

residential treatment facility Center where patients live and receive treatment appropriate for their particular needs; a children's residential treatment facility ideally furnishes both educational and therapeutic experiences for the emotionally disturbed child. Also called a halfway house.

residual Denoting a condition in which a person's acute mental symptoms have subsided.

residual schizophrenia Schizophrenia in which the patient no longer is psychotic but does have some remaining signs of the illness.

resistance Conscious or unconscious opposition to the uncovering of unconscious material; linked to underlying psychological defense mechanisms against impulses from the id that are threatening to the ego.

resistant attachment As described by Mary Ainsworth, a child's simultaneous yet antithetical wish for and avoidance of their mother's approach. *Compare* avoidant attachment; secure attachment.

resolution phase Final stage in the human sexual response cycle, as described by Masters and Johnson, during which the sexual system returns to its normal, nonexcited state following orgasm.

respondent conditioning CLASSICAL CONDITIONING. *See* conditioning.

restless legs syndrome (RLS) A syndrome characterized by an uncomfortable, subjective sensation of the limbs, usually the legs. Tends to be worse at night.

restricted affect Reduction in intensity of feeling tone that is less severe than in blunted affect but clearly reduced. *See* constricted affect.

retardation Reduction or slowing down of mental and physical activity, as often observed in depression. *See also* mental retardation.

retarded ejaculation INHIBITED MALE ORGASM.

retention *See* memory.

retroflexion Psychoanalytic term used notably by Sandor Rado to describe the turning of rage onto oneself.

retrograde amnesia Loss of memory for events preceding the onset of the amnesia. *Compare* anterograde amnesia.

retrospective falsification Memory becomes unintentionally (unconsciously) distorted by being filtered through a person's present emotional, cognitive, and experiential state.

retrospective study Investigation based on past data or past events, such as a case control study or a case history study.

Rett disorder A progressive condition characterized by deceleration in head growth, loss of purposeful hand movements, development of stereotyped hand movements (e.g., hand wringing), psychomotor retardation, loss of social engagement, loss of acquired speech, and ataxia between the ages of 6 months to 2 years.

reversal In psychoanalysis, an impulse's change from passive to active or from active to passive, as when a destructive impulse changes from masochism to sadism or vice versa.

right to refuse treatment Legal doctrine that holds that a person cannot be forced to have treatment against their will unless it is a life-and-death emergency.

right to treatment Legal principle that a facility that has assumed the responsibility of providing treatment is legally obligated to provide adequate treatment for a patient.

rigidity In psychiatry, a person's resistance to change, a personality trait.

risk factor Factor that accounts for the increased risk of a disorder. *See also* attributable risk; relative risk.

ritual **1.** Formalized activity practiced by a person to reduce anxiety, as in obsessive-compulsive disorder. **2.** Ceremonial activity of cultural origin.

ritualistic behavior Automatic behavior of cultural or psychogenic origin.

RLS Restless legs syndrome.

ROC Receiver operating characteristics.

Rogers, Carl R. (1902–1987) American psychologist who developed person-centered or client-centered theory of personality and psychotherapy, utilizing the concepts of self-actualization and self-direction; emphasized subjective experiential life of people and considered the self as a primary entity in both adjustment and maladjustment in people.

role Pattern or type of behavior developed under the influence of significant people in the person's environment. When the behavior pattern conforms to the expectations and demands of other people, it is said to be a complementary role; if it does not, it is known as a noncomplementary role. *See also* alternating role.

role playing Psychodrama technique in which persons are trained to function more effectively in their real-life roles. In the therapeutic setting of psychodrama, protagonists are free to try and to fail in their roles, for they are given the opportunity to try again until they succeed; new approaches to feared situations can thus be learned and applied outside the therapeutic setting.

Romberg sign Markedly increased swaying of the body or falling when a person stands erect with heels together and closes the eyes; typically indicates dysfunction of the dorsal column proprioceptive system, but it may also be seen in hysteria.

Rorschach Test Projective test, developed by Hermann Rorschach, in which the person is asked for associations in response to a series of inkblot pictures.

rumination Constant preoccupation with and thinking about a single idea or theme, as in obsessive-compulsive disorder.

rumination disorder of infancy Rare eating disorder of early childhood characterized by recurrent regurgitation of food in the absence of nausea, retching, or associated gastrointestinal disorder; regurgitated food is either ejected from the mouth or rechewed and reswallowed. Also called merycism.

Rush, Benjamin (1745–1813) Father of American psychiatry whose book, *Medical Inquiries and Observations upon the Diseases of the Mind* (1872), was the only American textbook on psychiatry until the end of the 19th century.

S

SAD Seasonal affective disorder.

sadism Paraphilia in which sexual gratification is achieved by inflicting pain or humiliation on a partner; first described by the French writer the Marquis de Sade (1740–1814). *See also* masochism; sadomasochistic relationship.

sadistic personality disorder Disorder in which a person shows a pervasive pattern of cruel, demeaning, and aggressive behavior whereby physical cruelty or violence is used to inflict pain on others and not to achieve some goal; such a person is fascinated by violence, weapons, injury, or torture. Not a DSM diagnosis.

sadomasochistic relationship Relationship in which the enjoyment of suffering by one person (masochism) and the enjoyment of inflicting pain by the other person (sadism) are important and complementary attractions in their ongoing interaction.

SAMHSA Substance Abuse and Mental Health Services Administration. A branch of the U.S. Department of Health and Human Services charged with improving the quality and availability of treatments and services for substance abuse and mental illnesses.

sample Research term for a subset of observations selected from a population.

sanatorium Institution where patients are treated for chronic physical or mental diseases or where they are attended to during a period of recuperation.

satyriasis Morbid, insatiable sexual needs or desires in a male; may be caused by organic or psychiatric factors. *Compare* nymphomania.

schedule of reinforcement Scheme of intermittent reinforcement in which a response is not reinforced every time it occurs. Four broad classes of intermittent schedules are based on either the number of responses required before an opportunity for reinforcement is presented or the passage of a certain amount of time before a given performance is reinforced (I) *fixed-ratio schedule,* in which reinforcement is delivered after a specified number of responses have occurred, for example, after every tenth response; (2) *variable-ratio schedule,* in which reinforcement is delivered on a schedule randomly changing around a given ratio, for example, after the third, sixth, then second response, and so on; (3) *fixed-interval schedule,* in which reinforcement is delivered contingent on the first required response after the elapse of a specified interval of time, for example, after every 10 minutes; and (4) *variable-interval schedule,* in which reinforcement is delivered after variable intervals of time have elapsed, for example, after 3, 6, then 2 hours, and so on. *See also* reinforcement.

schizoaffective disorder Psychotic disorder with signs and symptoms compatible with both a mood disorder and schizophrenia. In contrast to mood disorder with psychotic features, schizoaffective disorder is characterized by periods of at least 2 weeks without prominent mood symptoms.

schizoid fantasy Through fantasy, indulgence by a person in autistic retreat to resolve conflict and to obtain gratification; interpersonal intimacy is avoided and eccentricity serves to repel others. The individual does not fully believe in or insist on acting out the fantasies.

schizoid personality disorder Diagnostic category in DSM for persons with defects in the capacity to form social relationships but without other striking communicative or behavioral eccentricities. Also called introverted personality disorder.

schizophrenia Term introduced by Eugen Bleuler for a chronic, psychotic mental disorder of unknown etiology characterized by disturbances in thinking, mood, and behavior. The thinking disturbance is manifested by a distortion of reality, sometimes with delusions and hallucinations, accompanied by a fragmentation of associations that results in characteristic disturbances of speech; the mood disturbance includes ambivalence and inappropriate or constricted affective responses; the behavior disturbance may be manifested by apathetic withdrawal or bizarre activity. Subtypes of schizophrenia (disorganized, catatonic, paranoid, undifferentiated, and residual) are no longer formally in the DSM nomenclature, however they remain as useful descriptors. Formerly called dementia praecox.

schizophreniform disorder In DSM-5 a disorder similar to schizophrenia except that it lasts between 1 and 6 months.

schizotypal personality disorder Common term for mood disorder subtype characterized by depression, psychomotor slowing, hypersomnia, and hyperphagia that develops in autumn or winter and improves in spring and summer; not an official DSM-5 diagnosis.

schneiderian first rank symptoms Symptoms that Kurt Schneider, a German psychiatrist (1887–1967), considered to be of great pragmatic value in making a diagnosis of schizophrenia, including audible thoughts, arguing voices, thought withdrawal and insertion, delusions, and flat affect.

school phobia Young child's sudden fear of and refusal to attend school, usually considered a manifestation of separation anxiety but also may be a symptom of depression.

Schreber case One of Sigmund Freud's cases. Daniel Paul Schreber's published autobiographical account, entitled *Memoirs of a Neurotic* (1903), was analyzed by Freud (1911) and allowed him to decipher the fundamental meaning of paranoid processes and ideas, especially the relationship between repressed homosexuality and projective defenses.

scopophilia Sexual deviation in which a person achieves sexual gratification by viewing sexual acts or the genitals of others. *Compare* voyeurism.

scotoma **1.** In psychiatry, a figurative blind spot in a person's psychological awareness. *See also* blind spot. **2.** In neurology, a localized visual field defect.

screening Initial patient evaluation that includes medical and psychiatric history, mental status evaluation, and diagnostic formulation to determine the patient's suitability for a particular treatment modality.

screen memory Memory that serves as a cover-up for an associated painful memory.

SCT Sentence Completion Test.

SD Standard deviation.

SDA Serotonin-dopamine antagonist.

SDS Zung Self-Rating Depression Scale.

seasonal affective disorder (SAD) Mood disorder subtype characterized by depression, psychomotor slowing, hypersomnia, and hyperphagia that develops in autumn or winter and improves in spring and summer. **seasonal pattern**. *See* seasonal affective disorder.

secondary gain Obvious advantage that a person gains from an illness, such as gifts, attention, and release from responsibility. *Compare* primary gain.

secondary narcissism *See* narcissism.

secondary prevention *See* preventive psychiatry.

secondary process thinking In psychoanalysis, the form of thinking that is logical, organized, reality-oriented, and influenced by the demands of the environment; characterizes the mental activity of the ego. *Compare* primary process.

secondary retarded ejaculation After previous normal sexual functioning, the inability to ejaculate during coitus. *Compare* retarded ejaculation.

secondary sexual characteristics Physical characteristics, other than the external sexual organs, that distinguish male from female.

secure attachment As described by Mary Ainsworth, the positive, happy responses of a child following the mother's appearance.

sedative Drug that produces a calming or relaxing effect through central nervous system depression; for example, barbiturates, chloral hydrate, paraldehyde, and benzodiazepines. *Compare* hypnotic.

seizure An attack or sudden onset of certain symptoms, such a convulsions, loss of consciousness, and psychic or sensory disturbances; seen in epilepsy and can be substance induced. For types of seizures, see the specific term.

selection bias Nonrepresentative sampling resulting in erroneous conclusions.

selective inattention Harry Stack Sullivan's term for inattentiveness to anxiety-generating areas.

selective mutism Persistent failure to speak in one or more specific social situations.

selective serotonin reuptake inhibitors (SSRIs) Drugs that increase the concentration of serotonin in the brain; commonly used for the treatment of depression and anxiety disorders.

self Psychophysical total of a person at any given moment, including conscious and unconscious attributes. *See also* identity.

self-actualization Abraham Maslow's term for the inborn capacity of people to direct themselves in the healthiest way, toward a level of completeness.

self-analysis Investigation of one's own psychic components, which plays a part in all analysis, although to a limited extent, since few people are capable of sustaining independent and detached attitudes to the degree necessary for this approach to be therapeutic.

self-awareness Sense of knowing oneself, particularly in terms of insight into one's own psychodynamics; a major goal of most psychotherapies.

self-defeating personality disorder Disorder in which persons avoid or undermine pleasurable experiences and are drawn to situations or relationships in which they will suffer, even when better options are available; positive personal events are responded to with guilt or depression, reasonable offers of assistance from others are rejected, and anger or rejecting responses from others are invited, leaving them feeling hurt or humiliated. Also called masochistic personality disorder.

self-discovery In psychoanalysis, the freeing of the repressed ego in a person who has been brought up to submit to the wishes of the significant others around him.

self-fulfilling prophecy Situation in which one predicts a type of behavior that eventually one carries out.

self-help groups Groups composed of persons who want to cope with a specific problem or life crisis; characterized by homogeneity and cohesion.

self-image One's conception of one's own identity, personality, and worth as a person.

self-reference Denoting a person's repeatedly referring the subject under discussion back to himself.

self-system Harry Stack Sullivan's term for a personality system designed to ward off anxiety and preserve a positive view of the self.

SEM Standard error of the mean.

senescence Aging, as determined by inherent or hereditary factors.

senile dementia Dementia secondary to diffuse cerebral atrophy associated with advancing age; onset is insidious, progression is slow and gradual, and no specific therapy is known.

senium Period of old age, generally after age 65.

sensate focus learning In the treatment of sexual disorders, exercises that focus on heightening sensory awareness to touch, sight, sound, and smell.

sensation Feeling or impression when the sensory nerve endings of any of the six senses (taste, touch, smell, sight, kinesthesia, and sound) are stimulated.

sense of self One's feeling of individuality, uniqueness, and self-direction.

sensitivity In research, the probability of a positive test result in one who has the disorder. *Compare* specificity.

sensitivity training group Group in which members seek to develop self-awareness and an understanding of group processes, rather than to gain relief from an emotional disturbance. *See also* encounter group; T-group.

sensorimotor period *See* Piaget, Jean.

sensorium Hypothetical sensory center in the brain that is involved with clarity of awareness about oneself and one's surroundings, including the ability to perceive and process ongoing events in light of past experiences, future options, and current circumstances; sometimes used interchangeably with consciousness.

sensory aphasia Organic loss of ability to comprehend the meaning of words; fluid and spontaneous, but incoherent and nonsensical, speech. *See also* fluent aphasia and receptive aphasia.

sensory deprivation Lack of external stimuli and the opportunity for the usual perceptions; may be produced experimentally or may occur in real-life contexts (e.g., deep-sea diving, solitary confinement, loss of hearing or eyesight), leading to hallucinations, panic, delusions, and disorganized thinking. *See also* emotional deprivation.

sensory extinction Neurologic sign operationally defined as failure to report one of two simultaneously presented sensory stimuli, despite the fact that either stimulus alone is correctly reported. Also called sensory inattention.

sensory inattention SENSORY EXTINCTION.

Sentence Completion Test (SCT) Test designed to tap patients' conscious associations to areas of functioning in which the clinician may be interested; it is composed of a series (usually 75 to 100) of sentence stems, such as "I like….," "Sometimes I wish…," that patients are asked to complete in their own words.

separation anxiety Reaction expressed in a child who is isolated or separated from the mother, such as tearfulness, irritability.

separation anxiety disorder In DSM, an anxiety disorder characterized by an infant's or child's fear and apprehension on being removed from the parent or parent figure.

separation–individuation As elaborated by Margaret Mahler, the phase during which the child perceives itself as distinct from the mother; as the child separates, it becomes more independent and aware of its physical and psychological autonomy and can endure separation from the mother.

serotonin 5-Hydroxytryptamine (5-HT), an endogenous indolamines synthesized from dietary tryptophan and found in the gastrointestinal tract, the platelets, and the central nervous system. Evidence indicates that this monoamine serves as a neurotransmitter substance in the central nervous system and may play an important role in such diverse functions as sleep, sexual behavior, aggressiveness, motor activity, perception (particularly pain), and mood; dysfunction in central serotonergic systems has been proposed as a cause or factor in various mental disorders, including schizophrenia and the mood disorders.

serotonin-dopamine antagonists (SDAs) Drugs that block the receptors for both serotonin and dopamine in the brain. Also known as second-generation or atypical antipsychotics. *Compare* dopamine-receptor antagonists.

serotonin-norepinephrine reuptake inhibitors (SNRIs) Drugs that inhibit the reuptake of both serotonin and norepinephrine in the brain.

serotonin syndrome An excess of serotonin in the brain that causes a syndrome of confusion, delirium, tremor, and hyperthermia which may be fatal. Caused by overdose of serotonergic drugs.

serum levels *See* blood serum levels.

severe mental retardation *See* mental retardation.

sexual aberration Deviation from usual sexual practices. For types of sexual aberrations, see the specific term.

sexual arousal disorders Sexual dysfunction characterized by an inability to achieve a degree of sexual excitement sufficient to engage in coitus. Formerly called inhibited sexual excitement.

sexual aversion disorder Sexual desire disorder characterized by a disgust and/or avoidance of genital contact with a sexual partner.

sexual delusion Delusion centering on sexual identity, appearances, practices, or ideas.

sexual desire disorder Dysfunction characterized by a diminished or hypoactive sexual drive. Formerly called inhibited sexual desire. *See also* hypoactive sexual desire disorder; sexual aversion disorder.

sexual deviation PARAPHILIA.

sexual drive One of the two primal drives or instincts (the other is the aggressive drive) in Freud's dual-instinct psychoanalytic theory. It operates under the pleasure–unpleasure (pleasure–pain) principle, with its main goal being the preservation and maintenance of life, in contrast to the aggressive drive that follows the repetition–compulsion principle; its unconscious psychic energy is known as libido. Also known as life instinct; Eros.

sexual dysfunction Class of sexual disorders characterized by inhibitions in sexual desire or the psychophysiologic changes that characterize the sexual response cycle.

sexual identity Biologically determined sexual state. *Compare* gender identity.

sexualization Endowment of an object or function with a sexual significance that it previously did not have, or possessed to a lesser degree, in order to ward off anxieties associated with prohibited impulses or their derivatives.

sexual masochism *See* masochism.

sexual orientation distress Term that refers to a disorder characterized by persistent and marked distress about one's sexual orientation; most often characterized by a desire to acquire heterosexual rather than homosexual arousal.

sexual pain disorders Sexual dysfunction characterized by pain during coitus, such as dyspareunia and vaginismus.

sexual reassignment *See* transsexualism.

sexual sadism *See* sadism.

shaman Healer in a primitive tribe who uses supernatural or spiritual powers to cure the sick.

shame Failure to live up to self-expectation; often associated with fantasy of how person will be seen by others. *See also* guilt.

shaping Operant conditioning technique, used in behavior therapy, in which a behavioral goal is reached in stepwise fashion through selective reinforcement of closer and closer approximations of the desired behavior.

shared paranoid disorder *See* shared psychotic disorder.

shared psychotic disorder Rare disorder in which the delusion system of the patient has developed out of a close relationship with another person who had a previously established, similar delusional system. In DSM-5, this condition is called “delusional symptoms in partner of individual with delusional disorder.” It has historically been referred to as shared paranoid disorder, induced psychotic disorder, folie à deux, and double insanity.

shell shock Obsolete World War I term for an acute mental disorder arising as a consequence of combat experience. *See* posttraumatic stress disorder.

shift work circadian rhythm disorder Characterized by sleep pattern disruptions that result from night shift work; associated with insomnia, excessive sleepiness, or both.

shock treatment Obsolete term for convulsive therapy.

short-duration depressive episode A DSM-5 diagnosis characterized by depressed mood lasting between 4 and 14 days that is nonrecurring.

short-term memory Reproduction, recognition, or recall of perceived material within seconds to minutes after the initial presentation. Compare immediate memory; long-term memory.

shyness disorder AVOIDANT DISORDER OF CHILDHOOD OR ADOLESCENCE.

sibling One of two or more individuals having one common parent.

sibling rivalry Competition among siblings for the attention, affection, and esteem of their parents or for other recognition or reward.

sick role Use of illness or complaints about bodily functioning as a means of escaping personal failure and the expectation to succeed, or as a way of avoiding other social responsibilities. *See also* hypochondriasis.

side effect Action of a drug other than the desired therapeutic effect.

sign Objective evidence of a disease or disorder. *Compare* symptom.

signal anxiety Sigmund Freud’s term describing a type of anxiety characteristic of the psychoneuroses, in which a child learns to anticipate and react to the possibility of a traumatic situation before it becomes traumatic.

significant differences *See* statistical significance.

simple phobia Phobic disorder characterized by fear and avoidance of an object or situation not included in agoraphobia or social phobia.

simultanagnosia Impairment in the perception or integration of visual stimuli appearing simultaneously.

sitophobia Abnormal fear of eating.

skin-picking disorder *See* excoriation disorder.

Skinner, B. F. (1904–1990) American behavioral psychologist and author noted for his work on operant conditioning.

sleep Recurrent temporary period of relative unconsciousness, characterized by a reversible cessation of waking. Sensorimotor activity is accompanied by characteristic electroencephalographic changes; divided into REM (rapid eye movement) and non-REM (NREM) sleep.

sleep disorder Abnormality of the sleep–wake cycle. Sleep disorders include dyssomnias (insomnia disorder, primary insomnia, hypersomnia disorder, sleep–wake schedule disorder) and parasomnias (dream anxiety disorder, sleepwalking disorder, sleep terror disorder).

sleep-related eating disorder Sleep disorder characterized by the inability to fall back asleep after awakening without having something to eat or drink; predominantly affects infants and children.

sleep-related hallucinations Hallucinations that occur at sleep onset (hypnagogic) or on awakening (hypnopompic); hallucinations are often visual and common in patients with narcolepsy.

sleep-related hypoventilation Dyssomnia characterized by recurrent episodes of shallow breathing during sleep associated with insomnia and/or frequent arousal during the breathing disturbances. *See also* breathing-related sleep disorders.

sleep terror disorder Sleep disorder in which there are repeated episodes of abrupt awakenings from sleep, usually beginning with a panicky scream; characterized by verbalizations, confusion, autonomic activity, and poor recall of the dream. A non-REM sleep arousal disorder in DSM-5; also called pavor nocturnus; night terror. *See also* parasomnias.

sleep–wake schedule disorder Sleep disorder in which persons cannot sleep when they wish to sleep, but are able to sleep at other times; correspondingly, they cannot be fully awake when they want to be fully awake, but they are able to be awake at other times. Term used in ICD.

sleepwalking disorder DSM-5 term for somnambulism; a non-REM sleep arousal disorder. *See also* parasomnias.

slow-wave sleep (SWS) Non-REM sleep stages 3 and 4; so termed because of the characteristic wave appearance on the electroencephalogram (EEG) record. Also called delta sleep.

SNRI Serotonin-norepinephrine reuptake inhibitor.

social adaptation Adjustment to the whole complex of interpersonal relationships; the ability to live and express oneself in accordance with society's restrictions and cultural demands. *See also* adaptational approach.

social anxiety disorder *See* social phobia.

social breakdown syndrome Signs and symptoms indicating that the long-term institutionalization of a mental patient has itself contributed to the patient's symptoms; for example, development of progressive social and vocational incompetence, excessive passivity, and learning the chronic sick role.

social control Influence exerted on a person or a group of persons to conform to the demands or expectations of a society or any of its representative institutions, agencies, or organizations.

social instinct *See* herd instinct.

socialization Process through which an individual becomes a competent member of society; the condition in which inner impulses, that is, instincts, are expressed in conformity with cultural demands of the environment.

social learning theory Approach to behavior therapy that incorporates the elements of respondent and operant conditioning, but views cognitive processes as important mediators in such learning; relies on role modeling, identification, and human interactions.

social network therapy Type of therapy in which the therapist assembles all persons (relatives, friends, social relations, work relations) who have emotional or functional significance in the patient's life to provide feedback and support to the patient; all or some of the social network may be assembled at any given time. *See also* extended-family therapy.

social phobia Any of a variety of phobic disorders characterized by a fear of being observed by others (e.g., fear of public-speaking, blushing, eating in public, writing in front of others, using public lavatories). Also called social anxiety disorder. DSM-5 includes a "performance only" diagnostic category if the fear is limited to speaking or performing in public.

social psychiatry Branch of psychiatry concerned with ecologic, sociologic, and cultural variables that engender, intensify, or complicate maladaptive patterns of behavior and their treatment.

social (pragmatic) communication disorder Persistent failure to use verbal and nonverbal communication for social purposes; differentiated from Autism Spectrum Disorder

social therapy Rehabilitation therapy used with psychiatric patients to improve social functioning; for example, occupational therapy, therapeutic community, recreational therapy, milieu therapy, attitude therapy.

sociobiology Systematic study of the biologic basis of social behavior, pioneered by E. O. Wilson.

sociology Scientific study of group behavior and social organization.

sociometry Study and measurement of the interpersonal psychological structure of a group or society.

sociopath Obsolete term for a person with an antisocial personality disorder.

sociopathic behavior Former term for antisocial behavior.

sociotherapy Any treatment modality whose primary emphasis is on socioenvironmental and interpersonal factors; for example, the therapeutic community.

sodomy Anal intercourse. Legally, the term may include other sexual deviations as well, such as bestiality.

soldier's heart DA COSTA SYNDROME.

soma The body.

somatic delusion Delusion pertaining to the functioning of one's body.

somatic hallucination Hallucination involving the perception of a physical experience localized within the body.

somatic therapy Treatment of psychiatric disorders with biologic, organic, or physical treatments.

somatic symptom disorder Disorder characterized by multiple, recurrent physical complaints with no apparent physical cause and a preoccupation with the false belief of having a serious disease; symptoms have no demonstrable organic findings, are often misinterpreted by the patient, and are apparently linked to psychological factors. Previously called somatization disorder; also known as hypochondriasis; Briquet syndrome.

somatization disorder Somatoform disorder characterized by recurrent and multiple physical complaints with apparent physical cause; now called somatic symptom disorder in DSM-5. Also called Briquet syndrome.

somatoform disorders Term previously used for a group of mental disorders characterized by a marked preoccupation with the body and fears of disease; production of the symptoms is linked to psychological factors or conflicts but is not under voluntary control. Previously in DSM-IV, somatoform disorders included somatization disorder, conversion disorder, body dysmorphic disorder, and somatoform pain disorder. This group of disorders is now referred to as somatic symptom and related disorders. *See also* factitious disorder; malingering.

somatopagnosia Inability to recognize a part of one's body as one's own (also called ignorance of the body and autotopagnosia).

somatotype Physical build and structure of a person; one's physique.

somnambulism Repeated episodes of arising from bed during sleep, usually during the first third of the night during non-REM (stages 3 and 4 sleep); on awakening, the person has amnesia for the episodes. More frequently seen in males than in females, most commonly in children, who generally outgrow it; in adults, often associated with other psychiatric disturbances, such as schizoid personality disorder and schizophrenia.

somnolence Pathologic sleepiness or drowsiness from which one can be aroused to a normal state of consciousness.

spatial agnosia Inability to recognize spatial relations.

speaking in tongues Expression of revelatory message through unintelligible words; not considered a disorder of thought if associated with practices of specific Pentecostal religions. *See also* glossolalia.

specific developmental disorder *See* specific learning disorder.

specific learning disorders A class of neurodevelopmental disorders beginning in early childhood that are characterized by persistent difficulty or delays in learning skills in reading, written expression, and/or mathematics, which are inconsistent with the overall intelligence of the child. Specific learning deficit is indicated by the phrase, "with impairment in," either reading (dyslexia), written expression, or mathematics (dyscalculia). Previously called specific developmental disorder. *Compare* pervasive developmental disorder.

specificity In research, the probability of a negative test result in one who does not have the disorder.

specific reading disability DEVELOPMENTAL READING DISORDER.

speech disturbance Any of a variety of language and communication disorders not due to impaired function of speech muscles or organs of articulation.

speech sound disorder Language or speech disorder in which there is a consistent failure to correctly articulate a speech sound at the developmentally appropriate age in the absence of any underlying anatomical, physiologic, auditory, or neurologic abnormalities. Also called developmental articulation disorder, functional speech disorder, infantile perseveration, infantile articulation disorder, and phonologic disorder.

splitting Defense mechanism in which external objects are divided into “all good” and “all bad,” accompanied by the abrupt shifting of an object from one extreme category to the other.

SSRI Selective serotonin reuptake inhibitor.

stammering STUTTERING.

standard deviation (SD) Statistical measure of variability within a set of values so defined that, for a normal distribution, about 68% of the values fall within one SD of the mean, and about 95% lie within two SDs of the mean; sometimes represented by the Greek letter sigma (σ).

standard error of the mean (SEM) Statistical measure of how variable, that is, how reliable, a mean value calculated on the basis of a given sample is as an estimate of the mean of the population from which the sample was selected; obtained by dividing the standard deviation of the population by the square root of the number of measures in the sample.

standardized score Deviation of a score from its group mean expressed in standard deviation units. Also called z-score.

Stanford–Binet Intelligence Scale Primarily a verbal test of intellectual functioning, administered individually to children and adults, which emphasizes problem solving; one of the most widely used IQ tests.

startle reaction Reflex response to a sudden intense stimulus, consisting of a diffuse motor response involving flexion movements of the trunk and extremities and associated with a sudden increase in alertness; occurs in normal persons and in anxiety disorders.

state-dependent learning or memory Facilitated recall of information when one is in the same internal state (e.g., drug state) or external environment that the information was first acquired.

statistical inference Research term used to make a general statement about a study based on a small group or to decide whether to attribute differences between two groups to chance or to nonchance factors.

statistical significance Research term referring to an experimental result, based on a sample of observations, which demonstrates an outcome or effect of sufficient magnitude such that the probability of that result being due to chance alone is less than 5%. *See also* Type I error.

status epilepticus Continuous epileptic seizures. *See also* epilepsy.

stereotypy Continuous mechanical repetition of speech or physical activities; observed in cases of catatonic schizophrenia.

stereotypy and habit disorder *See* stereotypic movement disorder.

stereotypic movement disorder Motor disorder consisting of intentional, repetitive, and typically rhythmic behaviors that are nonfunctional, that is, serve no constructive, socially acceptable purpose (e.g., hand flapping, body-rocking, head-banging, face-slapping, skin picking). Movements appear self-soothing or self-stimulating, but in certain cases may also result in self-injury.

stilted speech Excessively formal, stiff, stylized, or pompous speech; overly polite, distant, or antiquated speech.

stimulant Drug that stimulates the central nervous system to produce increased psychomotor activity; for example, methylphenidate (Ritalin), caffeine, amphetamines.

stimulus Any event, internal or external to the person, which elicits some kind of nervous system activity or response.

Stockholm syndrome Syndrome in which captives identify with, and have sympathy for, their captors on whom they are dependent for survival; seen in terrorist–hostage situations. The major defense mechanism, as described by Anna Freud, was known as identification with the aggressor.

STP Slang name for 2,5-dimethoxy-4-methylamphetamine.

street drugs Readily available, illegally acquired psychoactive substances; for example, marijuana, heroin, cocaine, crack.

strephosymbolia Reading and writing disability characterized by confusion between similarly formed but oppositely oriented letters (as in b and d, p and q), with tendency to reverse the order of letters and words.

stress Circumstance in a person's life that causes tension or dysphoria. Stressors may be mild (e.g., termination of a friendship) or catastrophic (e.g., suicide of a spouse). DSM contains a Severity of Psychosocial Stressor Scale for children, adolescents, and adults. Also called psychosocial stressor.

stress immunity Failure to react to emotional stress.

stress reaction Disturbed psychological or physiologic functioning encountered when strong, involuntary, often unconscious internal impulses press for action that conflict with one's conscious, reality-oriented behavior.

stroke CEREBROVASCULAR ACCIDENT.

structured interactional group psychotherapy Group therapy developed by Harold Kaplan and Benjamin Sadock, in which the therapist provides a structural matrix for the group's interactions, the most important of which is that a different member of the group is the focus of the interaction in each session.

structured interview 1. Interview in which the same questions are asked of all patients. **2.** Interview in which the interviewer asks specific questions about specific topics.

Studies on Hysteria Title of a book by Josef Breuer and Sigmund Freud (1895) that described the cathartic method of treatment and the beginnings of psychoanalysis; demonstrated the psychological origins of hysterical symptoms and the possibility of effecting a cure through psychotherapy.

stupor 1. State of decreased reactivity to stimuli and less than full awareness of one's surroundings; as a disturbance of consciousness, it indicates a condition of partial coma or semi coma. **2.** In psychiatry used synonymously with mutism and does not necessarily imply a disturbance of consciousness; in catatonic stupor, patients are ordinarily well aware of their surroundings.

stuttering Speech disorder characterized by repetitions or prolongations of sounds, syllables, or words, or by unusual hesitations and pauses that disrupt the normal flow of speech. May often be associated with habitual eye blinking, facial grimacing, head jerks, or abnormal body movements. Also called stammering; child-onset fluency disorder.

subcoma therapy *See* insulin coma therapy.

subconscious
Obsolete term for the preconscious and the unconscious.

subjectivity State in which evaluation and interpretation are influenced by one’s own feelings and thinking.

sublimation Unconscious defense mechanism in which the energy associated with unacceptable impulses or drives is diverted into personally and socially acceptable channels; unlike other defense mechanisms, it offers some minimal gratification of the instinctual drive or impulse.

substance abuse Called substance use disorder in DSM-5; diagnosed according to the substance used, for example, alcohol, cocaine, cannabis, hallucinogens, inhalants, opioids, sedatives, stimulants, or tobacco. *See also* drug abuse.

substance use disorder A maladaptive pattern of substance use leading to impairments in functioning characterized by the substance being used in larger amounts over time; unsuccessful efforts to cut down use; cravings; and symptoms of tolerance and withdrawals.

substance withdrawal Cessation or reduction of intake of a substance regularly used to induce a state of intoxication.

substitution Unconscious defense mechanism in which a person replaces an unacceptable wish, drive, emotion, or goal with one that is more acceptable.

succinylcholine Powerful skeletal muscle relaxant used in anesthesia and as a muscle relaxant in electroconvulsive treatment.

suggestibility State of uncritical compliance with influence or of uncritical acceptance of an idea, belief, or attitude; commonly observed among persons with hysterical traits.

suggestion Process of influencing a person to the point of uncritical acceptance of an idea, belief, or other cognitive process.

suicidal ideation Thoughts or acts of taking one’s own life.

suicide Act of taking one’s own life. Although the underlying factors that lead a person to take their own life may not necessarily be fully understood by that person, the act of suicide is considered to be both voluntary and intentional.

suicide cluster *See* cluster suicide.

Sullivan, Harry Stack (1892–1949) American psychiatrist and psychoanalyst best known for his interpersonal theory of psychiatry.

sundowner's syndrome SUNDOWNING.

sundowning Syndrome in the older adults that usually occurs at night and is characterized by drowsiness, confusion, ataxia, and falling as the result of being overly sedated with medications. Also called sundowner's syndrome.

superego One of the three components of the psychic apparatus in the freudian structural framework, the others being the ego and id. It represents the internalized values, ideals, and moral attitudes of society and has psychic functions that are expressed in guilt, self-criticism, and conscience. It develops through the child's identification with his parents, and the severity of its prohibitions or demands is said to be related to the intensity and extent of resolution of the Oedipus complex. *See also* conscience.

supportive psychotherapy Psychotherapy that seeks to strengthen patients' defenses and to provide them with reassurance, rather than to probe deeply into their conflicts.

suppression Conscious act of controlling and inhibiting an unacceptable impulse, emotion, or idea; differentiated from repression in that repression is an unconscious process.

surrogate One who takes the place of another; a substitute.

susto Culture-specific mental syndrome seen in Latin America; characterized by an intense fear of evil supernatural forces.

SWS Slow-wave sleep.

symbiosis Dependent, mutually reinforcing relationship between two persons. Generally a normal, constructive characteristic of the infant–mother relationship, it can also occur in a destructive context, as between two mentally ill persons who reinforce each other's pathology or in a mother–infant relationship that induces in the child an intense separation anxiety, autism, and severe regression (symbiotic psychosis).

symbiotic psychosis Disorder in children characterized by an inability to separate psychologically or physically from the mother; such children experience confusion, intense separation anxiety, and an inability to function.

symbolization Unconscious defense mechanism in which one idea or object comes to stand for another because of some common aspect or quality in both; based on similarity and association; the symbols formed protect the person from the anxiety that may be attached to the original idea or object.

sympathetic nervous system The part of the autonomic nervous system innervating the viscera by outflow from thoracolumbar segments of the spinal cord. Its physiologic effects (e.g., tachycardia, peripheral vasoconstriction, pupillary dilation, decreased bowel motility) are predominantly adrenergic, and they characterize the fight-or-flight reaction that occurs in response to dangerous or threatening situations.

sympathomimetic drug Drug whose effects mimic the responses to stimulation of the sympathetic nervous system; for example, amphetamine, epinephrine.

sympathy Compassion for or sharing of another person’s feelings, ideas, and experiences. *Compare* empathy.

symptom Any abnormality indicative of a mental or physical disorder experienced by the patient but not observable by a physician. *Compare* sign.

symptomatic psychosis Brain dysfunction as a result of some general physical disease, the most common feature of which is a delirious state; may occur in the course of an acute infectious disease, such as pneumonia, influenza, or pelvic infections following childbirth.

symptom formation Unconscious psychic process in which a repressed impulse is indirectly released and manifested through a symptom; may be regarded as a kind of compromise reflecting a partial satisfaction of both the forbidden impulse and the ego reaction against it.

symptom substitution Phenomenon in which a set of symptoms that are removed directly in therapy, without regard for the unconscious conflicts responsible for their formation, are replaced by new symptoms. It has constituted a theoretical objection to such modalities as behavior therapy and hypnotherapy.

synapse Specialized structure at which one neuron makes contacts with the receptor elements in the adjacent neuron.

syncretic thought Jean Piaget's term for the prelogic, egocentric, solipsistic thinking that characterizes early childhood mentation. *See also* primary process.

synesthesia Condition in which the stimulation of one sensory modality is perceived as sensation in a different modality, as when a sound produces a sensation of color.

syphilis A chronic bacterial disease caused by the spirochete *Treponema pallidum* (*T. pallidum*). Associated with delirium, dementia, mania, psychosis, personality change, and depression.

syntactical (central) aphasia Aphasia characterized by difficulty in understanding spoken speech, associated with gross disorder of thought and expression.

syntaxic mode of experience Harry Stack Sullivan's term denoting the highest level of interpersonal communication, which is based entirely on reality and which is considered the desirable outcome of healthy development. *See also* secondary process.

syntropy Adolf Meyer's term characterizing healthy or wholesome relationships.

systematic desensitization Form of behavior therapy developed by Joseph Wolpe and others in which anxiety-evoking stimuli are represented to a patient in a state of deep muscle relaxation in an attempt to weaken the bond between the stimuli and the anxiety; particularly useful in the treatment of phobias. *See also* reciprocal inhibition and desensitization.

systematized delusion Group of elaborate delusions related to a single event or theme.

T

taboo Restrictions or prohibitions on behavior imposed by a culture, usually involving a dangerous, forbidden, or unclean entity.

tachylogia LOGORRHEA.

tactile amnesia *See* neurologic amnesia.

tactile hallucination Hallucination primarily involving the sense of touch. Also called haptic hallucination.

talion Retaliation; the fear that all bad deeds, intentional or accidental, will be punished in kind; that is, an eye for an eye and a tooth for a tooth. In psychoanalysis, the fear of castration or punishment for oedipal strivings, as in the Oedipus complex.

tangentiality Disturbance in which the person replies to a question in an oblique, digressive, or even irrelevant manner and the central idea is not communicated; failure to communicate the central idea distinguishes tangentiality from circumstantiality, in which the goal idea is reached in a delayed or indirect manner. The term has also been used synonymously with loosening of associations and speech derailment.

taphophobia Abnormal fear of being buried alive.

Tarasoff decision California Supreme Court decision that a physician or psychotherapist who has reason to believe that a patient may injure or kill someone must notify the potential victim, their relatives or friends, or the authorities.

tardive dyskinesia Late-appearing extrapyramidal syndrome associated with antipsychotic drug use and characterized by stereotyped involuntary movements of the lips, jaw, and tongue (tardive oral dyskinesia) and by other involuntary dyskinetic movements; symptoms may remit eventually or persist indefinitely after discontinuation of the medication, and the condition does not respond to treatment with antiparkinsonism drugs.

TAT Thematic Apperception Test.

telepathy Extrasensory perception of the mental activities of another person.

telepsychiatry Psychiatric practice using the electronic transmission of images.

temperament Inherent, constitutional predisposition to react, in a certain way to stimuli; variations in temperament are evident very early in life.

temporal lobe epilepsy COMPLEX PARTIAL SEIZURE.

temporary admission Hospitalization in which a person is admitted on the recommendation of one physician (which must be confirmed by a psychiatrist, upon admittance), for no more than 15 days if against their will; applies to patients who are so senile or confused that they require hospitalization and are notable to make decisions on their own, or so acutely disturbed that they must be immediately admitted to a psychiatric hospital on an emergency basis.

tension Physiologic or psychic arousal, uneasiness, or pressure toward action; an unpleasurable alteration in mental or physical state that seeks relief through action.

terminal insomnia Early morning awakening or waking up at least 2 hours before planning to. *Compare* initial insomnia; middle insomnia.

terrorism The use or threat of violence to instill fear with the intent to intimidate or coerce governments or societies in the pursuit of political, religious, or idealogic goals.

tertiary prevention *See* preventive psychiatry.

testamentary capacity One's competency to make a will. Three psychological abilities are necessary to demonstrate this competency: (1) the nature and extent of their bounty (property); (2) that they are making a will; and (3) who their natural beneficiaries are, for example, their spouse, children, and other relatives.

testimonial privilege Right to maintain secrecy or confidentiality in the face of a subpoena. Privilege belongs to the patient, not to the physician.

test of significance Statistical test used to determine whether a difference in the data obtained is due to chance or is meaningfully related to some specific factor or variable (statistically significant).

tetrahydrocannabinol (THC) Chemical substance produced by the Indian hemp plant (*Cannabis sativa*), believed to be responsible for most of the characteristic psychological effects of marijuana. Street drugs alleged to be THC frequently contain phencyclidine

(PCP), a veterinary tranquilizer that may produce extreme excitement, visual disturbances, and delirium.

T (training)-group Group that emphasizes training in self-awareness and group dynamics.

thanatology Study of death and matters leading up to and following it.

thanatophobia Abnormal fear of death.

Thanatos A term used by Freud to refer to the death instinct. *Compare* eros.

THC Tetrahydrocannabinol.

Thematic Apperception Test (TAT) Projective psychological test in which subjects supply interpretations of a series of ambiguous life situation drawings, based on their own feelings and attitudes and reflecting their unconscious conflicts and defensive structures.

theory Plausible or scientifically acceptable general principle or body of principles offered to explain phenomena.

therapeutic agent Anything that promotes healing, such as a substance, person, or apparatus.

therapeutic alliance Conscious contractual relationship between therapist and patient in which each implicitly agrees that they need to work together to help the patient with their problems; involves a therapeutic splitting of the patient’s ego into observing and experiencing parts. A good therapeutic alliance is especially necessary for the continuation of treatment during phases of strong negative transference.

therapeutic atmosphere All therapeutic, maturational, and growth-supporting agents, that is, cultural, social, and medical.

therapeutic community Institutional treatment setting designed with an emphasis on the importance of socioenvironmental and interpersonal influences in the therapy, management, and rehabilitation of the hospitalized mental patient. *See also* milieu therapy.

therapeutic group Group of patients joined together under the leadership of a therapist for the purpose of working together for psychotherapeutic ends; specifically, for the treatment of each patient’s mental disorders.

therapeutic role Position in which one aims to treat, bring about an improvement, or provide alleviation of a distressing condition or state.

therapeutic window Range of blood plasma levels of a drug within which optimal therapeutic effects occur, based on such factors as age, sex, race, genetic makeup, and concurrent medications.

therapist *See* psychotherapist.

tetracyclic antidepressants One group of antidepressant drugs so named because of their four-ringed structure. *See also* tricyclic antidepressants.

thinking *See* cognition.

thinking compulsion INTELLECTUALIZATION.

thioxanthene derivative One of a class of antipsychotic drugs closely related, both structurally and pharmacologically, to the phenothiazines; for example, chlorprothixene (Taractan), thiothixene (Navane).

third ear Ability to make use of intuition, sensitivity, and awareness of subliminal cues to interpret clinical observations of individual and group patients; a term introduced by the German philosopher Friedrich Nietzsche and later used in analytic psychotherapy by Theodor Reik.

third-party payer Health or medical care insurer.

thought broadcasting Feeling that one's thoughts are being broadcast or projected into the environment. *See also* thought withdrawal.

thought control *See* delusion of control.

thought deprivation BLOCKING.

thought disorder Any disturbance of thinking that affects language, communication, or thought content; the hallmark feature of schizophrenia. Manifestations range from simple blocking and mild circumstantiality to profound loosening of associations, incoherence, and delusions; characterized by a failure to follow semantic and syntactic rules which is inconsistent with the person's education, intelligence, or cultural background.

thought insertion Delusion that thoughts are being implanted in one's mind by other people or forces.

thought latency The period of time between a thought and its verbal expression. Increased in schizophrenia (*see* blocking) and decreased in mania (*see* pressured speech).

thought process disorder Symptom of schizophrenia, involving the intellectual functions, manifested by irrelevance and incoherence of verbal productions; ranges from simple blocking and mild circumstantiality to total loosening of associations, as in word salad.

thought withdrawal Delusion that one's thoughts are being removed from one's mind by other people or forces. *See also* thought broadcasting.

three-cornered therapy CO-THERAPY.

Three Essays on the Theory of Sexuality Title of a book by Sigmund Freud (1905) in which the libido theory was applied to the successive phases of psychosexual maturation in the infant, child, and adolescent; made possible the integration of a vast diversity of clinical observations and promoted the direct observation of child development.

Tic Seemingly involuntary sudden, brief, and rapid motor movements or vocalizations stimulated by an irresistible internal urge. Common motor tics include eye blinking, head-jerking, and grimacing; common vocal tics include coughing, throat-clearing, and grunting. Tics may have symbolic meaning. *See also* Tourette disorder.

tic disorders Predominately psychogenic class of motor disorders consisting of involuntary, spasmodic, stereotyped movements of a small group of muscles or vocal sounds; seen prominently in moments of stress or anxiety, and rarely as a result of organic disease. The two types of tic disorder in DSM-5 include Tourette disorder and persistent chronic motor or vocal tic disorders.

timidity Inability to assert oneself for fear of some fancied reprisal, even in the absence of objective evidence of potential harm.

tinnitus Noises in one or both ears, such as ringing, buzzing, or clicking; a rare side effect of some tricyclic antidepressant drugs.

TMS Transcranial magnetic stimulation.

tobacco dependence *See* nicotine dependence.

toilet training Program of teaching a child to control bladder and bowel functions; attitudes of both parent and child during the period may have important psychological implications for the child's later development.

token economy Program applying principles of operant conditioning to the management of an institutional setting, such as a ward or a classroom, during which reinforcement of desirable behavior is provided in the form of tokens or credits (conditioned reinforcers) that may be exchanged for a variety of positive reinforcers, such as food, television time, or a weekend pass.

tolerance Phenomenon in which, after repeated administration, a given dose of a drug produces a decreased effect or increasingly larger doses must be administered to obtain the effect observed with the original dose. *Compare* drug dependence.

tomography *See* computed tomography; positron emission tomography.

tonic convulsion Convulsion in which the muscle contraction is sustained.

topectomy Psychosurgical procedure involving ablation of a small and specific area of the frontal cortex for the treatment of a chronic psychotic patient.

torture The intentional infliction of physical and psychological suffering with the intent to gain information or to intimidate individuals or communities.

Totem and Taboo Title of a book by Sigmund Freud (1913) in which he applied his psychoanalytic concepts to the data of anthropology. He was able to afford much insight into the meaning of tribal organizations and customs, especially by invoking the Oedipus complex and the characteristics of magical thought as discovered from his studies of the unconscious.

Tourette syndrome Rare motor disorder, first described by a Paris physician, Gilles de la Tourette, that has its onset in childhood and is characterized by multiple involuntary muscle movements (tics), motor incoordination, and the presence of at least one vocal tic, such as echolalia and coprolalia.

toxicity State of being poisonous.

toxic psychosis Psychosis caused by toxic substances produced by the body or introduced into it in the form of chemicals or drugs.

toxophobia Abnormal fear of being poisoned.

trailing phenomenon Perceptual abnormality associated with hallucinogenic drugs in which moving objects are seen as a series of discrete and discontinuous images.

trainable Capable of achieving a certain degree of self-care and social adjustment at home and vocational usefulness in a closed supervised setting; describes the moderately mentally retarded (IQ of 35–40 to 50–55). *Compare* educable.

training group *See* T-group.

trait Distinguishing quality as an observed or measured characteristic of an individual.

trance Sleep-like state of reduced consciousness and activity.

tranquilizer Psychotropic drug that induces tranquility by decreasing anxiety or agitation, usually without clouding consciousness; formerly classified as major and minor tranquilizers which are now called antipsychotic and antianxiety agents, respectively.

transactional analysis Eric Berne's system of psychodynamic psychotherapy that focuses on the interactions (transactions) between the patient and the therapist in the treatment session and between the patient and others in a social environment; used in both individual and group psychotherapy. The system includes four components: (1) structural analysis of intrapsychic phenomena; (2) transactional analysis proper, the determination of the currently dominant ego state (parent, child, or adult) of each participant; (3) game analysis, identification of the games played in their interactions and of the gratifications provided; and (4) script analysis, uncovering of the causes of the patient's emotional problems.

transcranial magnetic stimulation (TMS) A form of brain stimulation in which a rapidly changing magnetic field is applied to the scalp to induce small, focused electrical currents in superficial cortex. Used for treatment-resistant depression.

transcultural psychiatry Branch of psychiatry concerned with the mental health of members of different cultures, that is, what may be considered normal for one culture may be unacceptable to another.

transference Unconscious tendency of a person to assign to others in the present and immediate environment those feelings and attitudes originally linked with significant figures in the person's early life, for example, identification of the therapist with a parent; the transference may be negative (hostile) or positive (affectionate). Analysis of transference phenomena is used as a major therapeutic tool in both individual therapy and group therapy to help patients better understand and gain insight into their behavior and its origins. *See also* countertransference; transference neurosis.

transference neurosis Phenomenon occurring in psychoanalysis in which the patient develops a strong emotional attachment to the therapist as a symbolized nuclear familial figure; repetition and the depth of that misperception or symbolization characterize it as a transference neurosis.

transsexualism Gender identity disorder in which a person has a desire to be of the opposite sex. Some transsexuals, many of whom have adopted the role of the opposite sex since childhood, have successfully undergone sex-changing surgical procedures, accompanied by intensive hormonal therapy and psychotherapy. *Compare* transvestism.

transvestism, transvestitism Paraphilia characterized by dressing in the clothing of the opposite sex for the purpose of sexual arousal; usually seen in men with a strong desire to appear as women. Also called cross dressing. *Compare* transsexualism.

trauma In psychiatry, a significant, upsetting experience or event that may precipitate or aggravate a mental disorder.

traumatic brain injury Damage to the structure of the brain caused by physical force that affects cognitive functioning with associated changes in mood and behavior. Most commonly associated with war injuries.

traumatic neurosis *See* posttraumatic stress disorder.

treated prevalence Number of persons being treated for a disorder in a defined geographic area.

tremor Rhythmical alteration in movement, which is usually faster than one beat a second; typically, tremors decrease during periods of relaxation and sleep and increase during periods of anger and increased tension.

trend of thought Thinking that centers on a particular idea associated with an affective tone.

triad Interactional relationship among three persons. Its prototype, the father–mother–child relationship, may evolve projectively in group therapy.

triadic therapy, triangular therapy CONJOINT THERAPY.

trichotillomania Compulsion to pull out one's hair.

tricyclic antidepressants One of a group of antidepressant drugs so named because of their three-ringed structure; currently the most widely used drugs for the treatment of depression, although anticholinergic side effects are prominent; for example, imipramine (Tofranil), amitriptyline (Elavil).

triskaidekaphobia The fear of the number 13.

trisomy Chromosomal aberration in which there are three chromosomes of one type instead of the usual two in an otherwise diploid cell, as in Down syndrome.

trisomy 21 syndrome DOWN SYNDROME.

true insight Understanding of the objective reality of a situation coupled with the motivational and emotional impetus to master the situation or change behavior.

t-test Statistical procedure designed to compare two sets of observations.

Tuke, William (1732–1822) British pioneer in the treatment of mental patients without the use of physical restraints.

Turner syndrome Disorder secondary to a chromosomal anomaly in which affected females typically have an XO sex chromosome constitution (instead of the usual XX) and a total of 45 chromosomes (instead of the usual 46). Classical somatic features include short stature, webbed neck, distinctive facies, sexual infantilism, and cubitus valgus. The incidence of mental retardation is not increased and severe psychopathic manifestations are uncommon, in contrast to the increased frequency of those disorders in XXY males. Also called ovarian dysgenesis; gonadal dysgenesis. *See also* Klinefelter syndrome.

twilight state Disturbed consciousness with hallucinations.

twin studies Studies that are useful in separating genetic and environmental influences and in looking for protective and precipitating factors.

twirling Sign present in autistic children who continually rotate in the direction in which their head is turned.

Type 1 error Research term referring to the rejection of the null hypothesis when it should have been retained. When the statistically calculated probability (p value) of making a Type 1 error on the basis of an experimental result is less than 0.05, the result is considered statistically significant; that type of error and the arbitrarily chosen 0.05 level of significance are sometimes called alpha (α) error. *Compare* Type 2 error.

Type 2 error Research term referring to the failure to reject a false null hypothesis, that is, concluding that any difference or effect demonstrated in an experiment is no greater than that expected by chance alone when, in fact, there is an actual difference or effect. Also called beta (β) error. *Compare* Type 1 error.

Type A personality As defined by Meyer Friedman and Ray Rosenman, cardiologists, an action-oriented individual who struggles to achieve poorly identifiable goals by means of competitive hostility; has increased amounts of low-density lipoprotein, serum cholesterol, triglycerides, and 17-hydroxycorticosteroids; and tends to develop coronary heart disease.

Type B personality As defined by Meyer Friedman and Ray Rosenman, cardiologists, a relaxed and less-aggressive individual (than Type A) who tends to strive less vigorously to achieve goals.

tyramine Sympathomimetic amine that acts by displacing stored transmitter from adrenergic axonal terminals; its degradation is normally aided by monoamine oxidase (MAO). Ingestion of food containing tyramine (e.g., cheese, beer, wine, yeast) by a patient on MAO inhibitors can provoke a potentially fatal hypertensive crisis.

U

UCR Unconditioned response or reflex.

UCS Unconditioned stimulus.

ultradian rhythm *See* biologic rhythm.

ululation Incoherent crying of a psychotic or hysterical patient.

unconditioned response, unconditioned reflex (UCR) *See* conditioning.

unconditioned stimulus (UCS) *See* conditioning.

unconscious **1.** One of three divisions of Sigmund Freud's topographic theory of the mind (the others being the conscious and preconscious) in which the psychic material is not readily accessible to conscious awareness by ordinary means; its existence may be manifested in symptom formation, in dreams, or under the influence of drugs. **2.** In popular but more ambiguous usage, any mental material not in the immediate field of awareness. **3.** Denoting a state of unawareness, with lack of response to external stimuli, as in a coma.

underachiever One who fails to perform at the level of their known potential or capability.

undersocialized Characterized by the absence of adequate social bonds to others, as a type of conduct disorder.

undifferentiated schizophrenia Type of schizophrenia with prominent psychotic symptoms that do not fall into the other schizophrenic subtypes; no longer included in DSM.

undoing Unconscious primitive defense mechanism, repetitive in nature, by which a person symbolically acts out in reverse something unacceptable that has already been done or against which the ego must defend itself; a form of magical expiatory action, commonly observed in obsessive-compulsive disorder.

unio mystica Feeling of mystic unity with an infinite power.

unipolar psychosis Mood disorder characterized by recurrent episodes of depression or, much more rarely, recurrent manic states. *Compare* bipolar disorder.

universality Total effect produced when all group therapy members share specific symptoms or problems.

unstructured interview **1.** Interview in which the interviewer chooses questions based on clinical judgment. **2.** Interview in which questions are related to what the patient brings up spontaneously.

urolagnia Paraphilia in which sexual pleasure is derived from urinating on someone else, being urinated on, or drinking urine.

utilitarian principle In policy and ethical decisions, a choice that is determined by whatever promises the greatest advantage to the common good.

utilization review committee Hospital committee that reviews the quality of services rendered, with particular attention to the appropriate use of facilities.

V

vagina dentata Sigmund Freud’s theory that an unconscious fantasy exists in certain persons who are afraid of women and who believe that there are “biting teeth” in the vagina.

vaginismus Painful vaginal spasms, usually psychogenic, that occur during coitus, causing dyspareunia; may have its onset during preparation for intercourse, making penile insertion impossible. *See also* Genito–pelvic pain/penetration disorder.

validity Degree to which a test measures what it claims to measure; the degree to which an experimental design yields data truly applicable to the phenomenon under investigation. *See also* reliability.

variable In research, any characteristic or factor that may assume different values. The terms “independent variable” and “dependent variable" indicate a relationship of cause and of effect, respectively.

variable-interval schedule *See* schedule of reinforcement.

variable-ratio schedule *See* schedule of reinforcement.

variance Statistical measure of the variability within a set of observations, defined as the sum of the squared deviations from the mean divided by the number of observations; it equals the standard deviation squared. *See also* analysis of variance.

variation Statistical term referring to the manner in which persons in a population vary among themselves with respect to a given quality or trait; variability of persons also affects the precision of sample estimates. Three common measures of variation are the range, the variance, and the standard deviation. Knowledge of variation in a population is important because it indicates how useful the mean value is as a representative figure.

vascular dementia A type of dementia in which a succession of strokes has led to a stepwise deterioration of intellectual functioning with associated focal neurologic signs and symptoms. Previously called multi-infarct dementia and currently called Major or Mild Vascular Neurocognitive Disorder in DSM-5-TR.

vegetative **1.** Pertaining to autonomic functions that are largely physiologic or concerned with the growth, nutrition, or general physical health and homeostasis of the organism. **2.** In depression, denoting characteristic symptoms such as sleep disturbance (especially early morning awakening), decreased appetite, constipation, weight loss, and loss of sexual response.

vegetative nervous system Obsolete term for autonomic nervous system.

velocardiofacial syndrome A genetic disorder caused by a microdeletion in chromosome 22. Characterized by cleft palate, heart defects, immune dysfunction, mild intellectual disability, psychotic disorders, and mood disorders. Also called Shprintzen syndrome or DiGeorge syndrome.

verbal amnesia *See* neurologic amnesia.

verbigeration Meaningless and stereotyped repetition of words or phrases as seen in schizophrenia. Also called cataphasia. *See* *also* perseveration.

verbiomania LOGORRHEA.

vertigo Sensation that one or the world around one is spinning or revolving; a hallmark symptom of vestibular dysfunction, not to be confused with dizziness.

visceral learning *See* biofeedback; learned autonomic control.

visual agnosia Inability to recognize objects or persons.

visual amnesia *See* neurologic amnesia.

visual hallucination Hallucination primarily involving the sense of sight.

visual motor gestalt test BENDER-GESTALT TEST.

vitamin therapy *See* orthomolecular psychiatry.

voice disorder A communication disorder that is characterized by abnormalities in vocal quality, pitch, and volume.

volitional Self-initiated.

volubility LOGORRHEA.

voluntary admission Hospitalization in which patients apply in writing for admission to a psychiatric hospital and are admitted if psychiatric examination reveals such need.

voluntary control Deliberate bringing about of an activity or refraining from an activity. The person exercising the control is aware of the nature of the activities and of the end to be achieved.

volunteer bias Sampling bias of persons who volunteer to take part in an experiment; such persons are not truly representative of the population and may tend to skew the results of the study, for example, the subjects may be more cooperative.

von Domarus principle Theory proposed by Eilhard von Domarus (1946) to explain schizophrenic thinking, which is characterized by the idea that two things are identical merely because they have identical predicates or properties.

voyeurism Paraphilia in which sexual excitement, frequently with orgasm, is obtained by looking at others naked, disrobing, or engaging in sexual activity. Also called voyeuristic disorder. *Compare* scopophilia.

W

WAIS Wechsler Adult Intelligence Scale.

Watson, John B. (1878–1958) American psychologist who used Ivan Pavlov's theory of classical conditioning to explain human behavior. *See also* Little Albert.

waxy flexibility Condition in which a person maintains the body position into which they are placed. Also called catalepsy.

Wechsler Adult Intelligence Scale (WAIS) Intelligence test that assesses intellectual functioning in adults.

Wechsler Intelligence Scale for Children (WISC) Intelligence test that assess intellectual functioning in children aged 5 to 15.

Wechsler Preschool and Primary Scale of Intelligence (WPPSI) Intelligence test that assesses intellectual functioning in children aged 4 to 6.

Wednesday Evening Society Small group of Sigmund Freud's followers who in 1902 started meeting with him informally on Wednesday evenings to receive instructions in psychoanalysis; as the society grew in numbers and importance, it evolved in 1910 into the Vienna Psychoanalytic Society.

weekend hospital Partial hospitalization in which the patient spends only weekends in the hospital and functions in the outside world during the week. *Compare* day hospital; night hospital.

Wernicke–Korsakoff syndrome Thiamine deficiency seen in Korsakoff psychosis (alcohol amnestic syndrome). Also called alcohol dementia. *See also* Wernicke fluent encephalopathy; Korsakoff psychosis.

Wernicke aphasia FLUENT APHASIA.

Wernicke fluent encephalopathy Neurologic disorder caused by nutritional deficiency of thiamine (vitamin B) as seen in chronic alcoholism, with hallmark clinical features of ophthalmoplegia, ataxia, and confusion; some patients show disorders of short-term memory and other cognitive functions characteristic of Korsakoff psychosis (alcohol amnestic disorder), which has come to be regarded as a more advanced and chronic stage of the same disease process. Wernicke encephalopathy responds dramatically to the administration of thiamine, which may also prevent progression into the largely irreversible Korsakoff psychosis.

Weyer, Johann (1515–1588) Dutch physician considered by some to be the first psychiatrist, whose interest in human behavior led to his writing *De Praestigiis Daemonum* (1563), a landmark in the history of psychiatry.

white-out syndrome Psychosis that occurs in Arctic explorers and mountaineers who are exposed to a lack of diverse stimuli in the snow-clad environment.

WHO World Health Organization.

Williams syndrome A genetic disorder associated with a microdeletion on chromosome 7 and is characterized by “elfin-like” facial features, mild or moderate intellectual disability, cardiovascular disease, hyperacusis, hypercalcemia, and neuromusculoskeletal and renal abnormalities.

Wilson disease An autosomal recessive genetic disorder that causes excessive amounts of copper in the liver or brain. Patient may show psychological symptoms such as depression, suicidal ideation, and aggression. Is fatal without treatment.

windigo Culture-specific syndrome seen in Canadian Indians, characterized by a delusion of transformation into or possession by a windigo (wihtigo), a feared supernatural cannibalistic monster.

WISC Wechsler Intelligence Scale for Children.

withdrawal 1. Pathologic retreat from interpersonal contact and social involvement; extreme decrease of intellectual and emotional interest in the environment. It may be seen in schizophrenia and depression. **2.** *See* substance withdrawal.

withdrawal syndrome Stereotyped constellation of signs and symptoms that appears when a person stops taking a drug or chemical substance on which they have become physically dependent. It is more likely to appear immediately after abrupt discontinuation, but may also appear a few days later; specific clinical features are characteristic for the particular drug or substance. Also called abstinence syndrome; discontinuation syndrome.

word approximation Use of conventional words in an unconventional or inappropriate way (metonymy) or of new words that are developed by conventional rules of word formation (e.g., “handshoes” for gloves and “time measure” for clock); distinguished from a neologism, which is a new word whose derivation cannot be understood. *See also* paraphasia.

word association technique Technique devised by Carl Jung, who presented stimulus words to patients and had them respond with the first word that came to mind; it gives insight into persons’ unconscious or subconscious thinking.

word blindness Obsolete word for alexia.

word salad Incoherent, essentially incomprehensible mixture of words and phrases commonly seen in far-advanced cases of schizophrenia. *See also* incoherence.

working through In psychoanalysis, the repeated and varied examination of a conflict, neurotic trend, or other problem for the purpose of increasing insight into unconscious processes and effecting adaptive personality changes; constitutes a fundamental facet of the psychoanalytic process.

World Health Organization (WHO) Specialized agency of the United Nations, established in 1948, governed by the World Health Assembly. Technical committees and regional organizations further the purpose of the WHO: “the attainment by all people of the highest level of health.” It publishes the *International Classification of Diseases* (ICD).

World Psychiatric Association (WPA) International association, encompassing psychiatric associations from 75 countries throughout the world, whose objectives are to strengthen and promote international cooperation in psychiatry and among psychiatrists working in different fields and to encourage the exchange of information concerning psychiatric disorders.

WPA World Psychiatric Association.

WPPSI Wechsler Preschool and Primary Scale of Intelligence.

X-Y-Z

xenophobia Abnormal fear of strangers.

yohimbine Drug that blocks adrenergic α-receptors; because of its parasympathetic effect that causes vasodilatation, it has been used as an agent to help induce penile erection.

York retreat One of the earliest hospitals for the mentally ill, founded in 1792 in York, England, by William Tuke and other Quakers.

yttrium-90 Radioisotope that has been implanted experimentally in the brain to destroy certain tracts and areas in an effort to improve severe mental disorder.

zeitgeist German word for the general intellectual, moral, and cultural climate of an era.

zoophilia Paraphilia in which animals are used to produce sexual excitement. *See also* bestiality.

zoophobia Abnormal fear of animals.

z-score STANDARDIZED SCORE.

Zung Self-Rating Depression Scale (SDS) Twenty-item report in which the patient answers questions about symptoms of depressive disorders such as sleep patterns, appetite disturbance, libido, irritability, and hopelessness.

zygote Fertilized egg produced by the union of two cells (sperm and ovum) to form a diploid cell in sexual reproduction.

zygotic Pertaining to a zygote or to the individual developing from such a fertilized egg.

Appendix C

Comparative Diagnoses

The following tables summarize the key features of the most common psychiatric diagnoses.

The columns compare the diagnoses of the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, Text Revision (DSM-5-TR) (2022), International Statistical Classification of Diseases and Related Health Problems 10th Revision (ICD-10), 2019 version which is still in use in the United States, and the International Statistical Classification of Diseases and Related Health Problems 11th Revision (ICD-11) (2022).

The rows list the domains common to most diagnostic systems: Diagnostic name, Duration (if required), Symptoms, Required number of symptoms, Psychosocial consequences (of the disorder), Exclusions (the symptoms are not better explained by____), Symptom specifiers, Course specifiers, Severity specifiers, and additional comments. In cases where no system commons on that domain, the row is omitted.

The tables are meant to compare diagnostic approaches and are not intended as a substitute for the actual criteria. The reader is referred to the source materials for the criteria.

Not all diagnoses are included here. For example, the three classification system includes secondary disorders (“due to a medical condition,” “due to a substance”), which should be used if the evaluation determines that the symptoms are better explained by a medical condition or the effects of a medication or substance. They also include “Other” and “Unspecified” categories to include cases of clinically significant symptoms that do not meet the full criteria, or there is insufficient information, or the clinician chooses not to specify why the criteria are not met. In both cases, those diagnoses are omitted here.

1. NEURODEVELOPMENTAL DISORDERS

Intellectual Disabilities

Table 1.

Intellectual Disability (Intellectual Developmental Disorder)/Disorders of Intellectual Development

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Intellectual disability (intellectual developmental disorder)	Mental retardation	Disorders of intellectual development
Symptoms	▸ Deficits in reasoning, abstraction, judgment, learning ▸ Deficits in adaptive functioning causing failure to meet developmental milestones for independence and social functioning ▸ Deficits arise during the developmental period	An arrest or incomplete development of ≥1 of the skills contributing to overall intelligence: cognitive, language, motor, and social abilities	▸ The presence of significant limitations in intellectual functioning across various domains such as perceptual reasoning, working memory, processing speed, and verbal comprehension. ▸ The presence of significant limitations in adaptive behavior, which refers to the set of conceptual, social, and practical skills that have been learned and are performed by people in their everyday lives ▸ Onset occurs during the developmental period.
Severity specifiers	**Mild** **Moderate** **Severe** **Profound**	**Mild** **Moderate** **Severe** **Profound**	**Mild** **Moderate** **Severe** **Profound**
Comments	**Unspecified diagnosis**. Unspecified intellectual developmental disorder (intellectual disability) for persons >5 years, and assessment is difficult or impossible due to sensory or other physical impairments		**Disorder of intellectual development, provisional.** Assigned when there is evidence of a disorder of intellectual development but the individual is an infant or child under the age of 4, making it difficult to ascertain whether the observed impairments represent a transient delay. Disorders of intellectual development,

unspecified.

Table 2.
Global Developmental Delay

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Global developmental delay	Disorder or developmental (global delay)	Disorders of intellectual development, unspecified
Symptoms	Failure to meet developmental milestones before the age of 5, with inability to perform full assessment of testing of intellectual functioning	Classified as an unspecified disorder	

Communication Disorders

Table 3.
Language Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Language disorder	Specific developmental disorders of speech and language	Developmental language disorder
Duration	Onset in the early developmental period	Onset in the early developmental period	Onset in the early developmental period
Symptoms	▸ Reduced vocabulary ▸ Limited sentence structure ▸ Impairments in discourse Difficulties are substantially below that expected for that age group	General category that includes the communication disorders listed below, including articulation, expressive, and receptive disorders	Persistent deficits in the acquisition, understanding, production, or use of language (spoken or signed) beyond that expected for the age. This includes deficits in the following: ▸ Phonologic awareness ▸ Syntax, morphology, or grammar ▸ Semantics ▸ Narrative or conversational discourse ▸ Pragmatics
Required number of symptoms	Any of the above		Any of the above
Psychosocial consequences	Limitations in communication affect social, academic, and occupational functioning		Limitations in communication affect social, academic, and occupational functioning
Exclusions	Sensory impairment, motor dysfunction, or medical or neurologic condition		Disorders of intellectual development, autism spectrum disorder, other neurodevelopmental disorders, Sensory impairment, motor dysfunction, or medical or neurologic condition
Symptom specifiers			With impairment of receptive and expressive language With impairment of mainly expressive language

			With impairment of mainly pragmatic language With other specified language impairment

Table 4.
Speech Sound Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Speech sound disorder	Expressive language disorder	Developmental speech sound disorder
Duration	Onset in the early developmental period		Onset in the early developmental period
Symptoms	Difficulty with speech sound production (articulation of phonemes).	The child's ability to use expressive spoken language is markedly below the appropriate level for its mental	Persistent errors of pronunciation, articulation, or phonology
Psychosocial consequences	Limitations in communication affect social, academic, and occupational functioning		Limitations in communication affect social, academic, and occupational functioning
Exclusions	Not due to congenital/acquired conditions affecting speech (cerebral palsy, cleft palate), sensory impairment, or other medical or neurologic condition		Not due to congenital/acquired conditions affecting speech (cerebral palsy, cleft palate), sensory impairment, or other medical or neurologic condition

Table 5.
Childhood Onset Fluency Disorder (Stuttering)

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Childhood onset fluency disorder (Stuttering)	Stuttering (stammering)	Developmental speech fluency disorder
Duration	Onset of symptoms during the developmental period		Onset of symptoms during the developmental period
Symptoms	Fluency and speech abnormalities as evidenced by: ▶ Repetition of sounds and/or syllables ▶ Prolonging sounds or consonants ▶ Using broken words ▶ Blocking or pausing ▶ Frequent word substitution (circumlocution) ▶ Excess physical tension during word production ▶ Repeating monosyllabic words	Speech is characterized by repetition or prolongation of sounds or words or by frequent pauses, resulting in disruption or normal flow or rhythm of speech.	Frequent or pervasive disruption of the normal rhythmic flow and rate of speech, including: ▶ repetitions and prolongations in sounds, syllables, words, and phrases ▶ as well as blocking (inaudible or silent fixations or inability to initiate sounds) ▶ word avoidance or substitutions
Psychosocial consequences	Causing severe anxiety and/or impairment in areas of functioning		Limitations in communication affect social, academic, and occupational functioning
Exclusions	Result of: ▶ Speech-motor or sensory issues ▶ Neurologic injury ▶ Another medical condition ▶ Another mental disorder Note: later-onset cases after the developmental period are coded as “adult-onset fluency disorder”	Result of: Tic disorders	Disorder of Intellectual Development Disease of the Nervous System Sensory impairment Structural abnormality

Table 6.
Social (Pragmatic) Communication Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Social (pragmatic) communication disorder	Developmental disorder of speech and language, unspecified	Listed as a specifier for developmental language disorder (with impairment of mainly pragmatic language)
Symptoms	Difficulties with using verbal or nonverbal communication in social situations, as evidenced by: ▶ Difficulty greeting others or sharing information with others ▶ Difficulties matching tone or context in a conversation ▶ Difficulty following social rules and expectations in conversations ▶ Difficulties understanding implicit meaning in conversations Onset of symptoms in the early developmental period		
Psychosocial consequences	Causing functional limitation		
Exclusions	Another medical or neurologic condition Autism spectrum disorder Intellectual disability or global developmental delay Another mental disorder		

Table 7.
Unspecified Communication Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Unspecified communication disorder	Developmental disorder of speech and language, unspecified	Developmental speech or language disorders, unspecified
Symptoms	Limitations in communication not meeting criteria for other disorders		
Psychosocial consequences	Limitations in communication affect social, academic, and occupational functioning		
Comments	Used for cases in which the clinician chooses not to specify reasons for the disorder or there is insufficient information.		

Autism Spectrum Disorder

Table 8.
Autism Spectrum Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Autism spectrum disorder	Childhood autism	Autism spectrum disorder
Symptoms	Symptoms of difficulties/deficits in social interaction, as evidenced by: ▶ Deficits in emotional reciprocity or failure to respond appropriately in social interactions ▶ Deficits in nonverbal communication, eye contact, body language/gesturing, and/or facial expression ▶ Deficits in forming, developing, or maintaining relationships or friendships Restricted and/or repetitive behaviors or interests, such as in: ▶ Stereotyped motor movements ▶ Inflexibility with regard to daily routines or rituals ▶ Restricted or fixed interests ▶ Hyper- or hyporeactivity to sensations or sensory stimuli Symptoms present in the early developmental period	Pervasive disorder of development involving ▶ Abnormal development present before the age of 3 ▶ Abnormal social functioning, communication, and repetitive/restricted behaviors	Persistent deficits in initiating and sustaining social communication and interactions outside the range for that age. May include limitations in: ▶ Understanding or responding to verbal or nonverbal communication ▶ Understanding or using language in a social context ▶ Social awareness ▶ Ability to imagine or respond to feelings ▶ Mutual sharing of interests ▶ Ability to make and sustain peer relationship Persistent restricted, repetitive, and inflexible patterns of behavior, interests, or activities that are inappropriate or excessive for the social context. These may include persistent: ▶ Lack of adaptability to new experiences or circumstances ▶ Inflexible adherence to routines ▶ Excess adherence to rules ▶ Excess and persistent ritualized patterns of behavior ▶ Repetitive and stereotyped motor movement

			▶ Preoccupation with ≥1 special interests, parts of objects, or stimuli ▶ Hyper or hyposensitivity to sensory stimuli or unusual interest in the stimuli
Required number of symptoms	All three of the above criteria met		
Psychosocial consequences	Marked impairment in functioning		Marked impairment in functioning
Exclusions	Result of: ▶ Intellectual disability ▶ Global developmental delay		Rett syndrome
Symptom specifiers	***With or without accompanying intellectual impairment*** ***With or without accompanying language impairment*** ***Associated with another neurodevelopmental, mental, or behavioral disorder*** ***With catatonia***		With or without accompanying intellectual impairment With or without accompanying language impairment ▶ With mild or no impairment of functional language ▶ With impaired functional language ▶ With complete, or almost complete, absence of functional language
Severity specifiers	For social impairment: **mild, moderate, severe** For behavior patterns: **mild, moderate, severe**		
		NOTE: atypical autism–symptoms do not meet all diagnostic criteria for childhood autism NOTE: Asperger syndrome—difficulties in social interaction similar to that found in autism, in addition to restricted interests;	

however, no deficits in language or cognition are seen

Attention-Deficit/Hyperactivity Disorder

Table 9.
Attention-Deficit/Hyperactivity Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Attention-deficit/hyperactivity disorder	Hyperkinetic disorders Disturbance of activity and attention	Attention-deficit hyperactivity disorder
Duration	6 months or longer		Persistent for ≥6 months, begins before age 12 (usually)
Symptoms	A persistent pattern of either or both of inattention, as evidenced by: ▶ Failure to give attention to details or making frequent mistakes ▶ Difficulty maintaining attention or focus ▶ Not seeming to listen when spoken to ▶ Failing to follow through with tasks or instructions ▶ Difficulty organizing tasks ▶ Avoiding or delaying tasks that require sustained mental effort or attention ▶ Frequently losing or misplacing items ▶ Easily distracted ▶ Forgetfulness Hyperactivity/impulsivity, as evidenced by: ▶ Fidgeting or restlessness ▶ Inability to remain in a seat ▶ Running around or climbing in inappropriate social situations ▶ Inability to engage in quiet play or activities ▶ Difficulty remaining still or inactive ▶ Talking excessively ▶ Blurting out answers without waiting for their turn	Early onset (usually before the age of 5) of inability to engage in activities requiring prolonged attention, in addition to disorganization of task completion and excessive activity. There may also be associated impulsivity, recklessness, and social disinhibition.	▶ Inattention symptoms and/or a combination of hyperactivity and impulsivity symptoms ▶ Outside the limits of normal variation expected for age and level of intellectual development ▶ Symptoms vary according to chronologic age and disorder severity ▶ Occur in a variety of settings Inattention ▶ Difficulty sustaining attention ▶ Easily distracted ▶ Loses things Hyperactivity ▶ Excess motor activity ▶ Difficulty engaging in activities quietly ▶ Blurts out answers in school ▶ Inappropriately acts out in response to stimuli

	▶ Difficulty waiting for one’s turn ▶ Frequently interrupting others Symptoms present before the age of 12, with symptoms present in ≥2 settings		
Required number of symptoms	≥6 symptoms of inattention (≥5 for adolescents/adults) and/or ≥6 of hyperactivity-impulsivity (≥5 for adolescents/adults)		
Psychosocial consequences	Impairment in functioning		Impairment in functioning
Exclusions	Result of: ▶ Other mental illness		Another mental disorder Substance or medication
Symptom specifiers	***Combined presentation*** ***Predominantly inattentive presentation*** ***Predominantly hyperactive/impulsive presentation***		Combined presentation Predominantly inattentive presentation Predominantly hyperactive/impulsive presentation
Course specifiers	***In partial remission (full/all criteria not met for prior 6 months, though symptoms still causing significant impairment)***		
Severity specifiers	**Mild** (few symptoms in excess of the minimum required for diagnosis, in addition to only minor impairment at most in functioning) **Moderate** (intermediate severity/impairment) **Severe** (several symptoms of high severity and resulting in marked impairment)		
	Other specified attention-deficit/hyperactivity	Hyperkinetic conduct disorder—referring to symptoms present in	**Other specified attention-**

	disorder reserved for cases where above symptoms cause distress or impairment but do not meet full criteria for a diagnosis **Unspecified attention-deficit hyperactivity** disorder is reserved for cases in which symptoms do not meet full criteria, and clinician chooses not to specify reasons for the disorder, or there is insufficient information	the context of conduct disorder	**deficit/hyperactivity disorder** **Unspecified attention-deficit hyperactivity**

Learning Disorders

Table 10.
Specific Learning Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Specific learning disorder	Specific developmental disorders of scholastic skills Specific reading disorder Specific spelling disorder Specific disorder of arithmetical skills Mixed disorder of scholastic skills	Developmental learning disorder
Duration	≥6 months		Onset in early school years
Symptoms	Difficulties with learning or academics, below what would be expected per individual's age or school level, as evidenced by: ▶ Inaccuracy or slowness with reading ▶ Difficulty understanding or comprehending what is being read ▶ Trouble with spelling ▶ Difficulty with written expression ▶ Difficulties with numbers or calculation ▶ Difficulties with mathematical reasoning Symptoms begin during school-age years (but may become obvious during the later part of academic career)		The presence of significant limitations in learning academic skills of reading, writing, or arithmetic, resulting in a skill level markedly below what would be expected for age
Required number of symptoms			
Psychosocial consequences	Impairment in functioning		Significant impairment to academic, occupational, or other areas of functioning
Exclusions	Result of:		External factors

	▸ Intellectual disability ▸ Visual or auditory impairment ▸ Another mental disorder ▸ Another medical disorder ▸ Psychosocial adversity ▸ Result of inadequate educational instruction	(economic, environmental disadvantage, lack of access to educational opportunities) Disorders of intellectual development, other neurodevelopmental disorders, and motor or sensory disorders
Symptom specifiers	***With impairment in reading*** ***With impairment in written expression*** ***With impairment in mathematics***	Impairment in reading Impairment in written expression Impairment in mathematics
Course specifiers		
Severity specifiers	**Mild** (minimal accommodations or support needed during school) **Moderate** (some accommodations needed) **Severe** (intensive individualized and specialized teaching needed for most of the schooling)	
Comments		Other specified impairments in learning Developmental learning disorder, unspecified

Motor Disorders

Table 11. Developmental Coordination Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Developmental coordination disorder	Specific developmental disorder of motor function	Developmental motor coordination disorder
Duration	Onset in the early developmental period		Onset in the early developmental period
Symptoms	The development of coordinated motor skills is far behind what would be expected for an individual's chronologic age	Significant impairment in motor coordination	Significant delay in the acquisition of gross or fine motor skills and impairment in the execution of coordinated motor skills. May manifest as ▶ Clumsiness ▶ Slowness ▶ Inaccuracy of motor performance. Coordinated motor skills are markedly below that expected on the basis of age.
Required number of symptoms			
Psychosocial consequences	Resulting in impaired ability to play, perform self-care, and function.		Limitations in activities of daily living, school work, vocation, leisure activities, or other important areas of functioning
Exclusions		General intellectual retardation Any specific congenital or neurologic disorder	Disease of the nervous system Disease of the musculoskeletal system Connective tissue disease Sensory impairment Disorder of intellectual development
Symptom specifiers	Result of: ***Another neurologic condition*** ***Intellectual disability*** ***Visual impairment***		

Table 12.
Stereotypic Movement Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Stereotypic movement disorder	Stereotyped movement disorders	Stereotyped movement disorder
Duration			Onset in the early developmental period. Persists ≥several months
Symptoms	Repetitive and seemingly purposeless movements with onset during the developmental period	The presence of voluntary, repetitive, stereotyped, and seemingly purposeless movements outside of any other psychiatric or neurologic condition; may include such things as repeatedly rocking, hand-flapping, or biting	Voluntary, repetitive, stereotyped, apparently purposeless, and often rhythmic movements
Required number of symptoms			
Psychosocial consequences	Marked interference in activities and functioning		Marked interference in activities and functioning or result in self-inflicted injury
Exclusions	Other medical condition Substance- or medication-induced, including withdrawal Other mental disorder	Tic disorder Trichotillomania Stereotypies that are part of a broader psychiatric condition Nail biting Nose-picking Movement disorders of organic origin	
Symptom specifiers	With self-injurious behavior Without self-injurious behavior Associate with a known medical or genetic condition, neurodevelopmental disorder, or environmental factor		With self-injury Without self-injury
Course specifiers			
Severity specifiers	**Mild** (symptoms easily suppressed by sensory stimulus or distraction)		

	Moderate (significant behavioral modification needed to control symptoms) **Severe** (continuous measures taken to prevent harm or injury)	
Comments		Stereotyped movement disorder, unspecified

Tic Disorders

Table 13.
Tourette Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Tourette disorder	Combined vocal and multiple motor tic disorder (de la Tourette)	Tourette syndrome
Duration	Despite waxing or waning, symptoms have been present for ≥1 year since the initial onset		≥1 year. Onset in developmental period.
Symptoms	Presence of both motor and vocal tics over the course of illness, with onset <age 18	Tic disorder involving multiple motor ticks and ≥1 more vocal tics; symptoms present in childhood or adolescence and tend to persist into adulthood.	The presence of both motor tic(s) and phonic tic(s) that may or may not manifest concurrently or continuously during the symptomatic course. Motor and phonic tics are defined as sudden, rapid, nonrhythmic, and recurrent movements or vocalizations, respectively.
Exclusions	Other medical condition Substance- or medication-induced, including withdrawal		Another medical condition (e.g., Huntington disease) Substance or medication on (e.g., amphetamine), including withdrawal effects (e.g., from benzodiazepines).
Comments	If symptoms of ONLY motor OR vocal tics, the diagnosis would be “Persistent (Chronic) Motor or Vocal Tic Disorder”		

Table 14.
Persistent (Chronic) Motor or Vocal Tic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Persistent (chronic) motor or vocal tic disorder	Tic disorder	▶ Chronic motor tic disorder ▶ Chronic phonic tic disorder
Duration	Despite waxing or waning, symptoms have been present >1 year since the initial onset		≥1 year
Symptoms	Presence of either motor or vocal tics over the course of illness, but not both. Onset before the age of 18	Presence of a tic, defined as an involuntary, fast, repeated, and nonrhythmic motor movement or vocal production that is sudden and seemingly purposeless. Such tics are experienced as urges that are strong, but that can be suppressed variably	Motor and vocal tics are defined as sudden, rapid, nonrhythmic, and recurrent movements or vocalizations, respectively
Required number of symptoms			
Psychosocial consequences			
Exclusions	Other medical condition Substance- or medication-induced, including withdrawal		
Symptom specifiers			
Course specifiers		Transient tic disorder (lasting <12 months) Chronic motor or vocal tic disorder (lasting longer than a year)	
Severity specifiers			
Comments	If symptoms are less than 1 year, the diagnosis would be **provisional tic disorder** **Other specified tic disorder** is reserved for cases in which symptoms do not meet full criteria, and the	Chronic motor or vocal tic disorder (lasting longer than a year)	

	clinician chooses not to specify reasons for the disorder, or there is insufficient information.	

2. SCHIZOPHRENIA SPECTRUM DISORDERS

Table 15.
Delusional Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Delusional disorder	Delusional disorder	
Duration	≥1 month	Does not specify	Typically ≥3 months
Symptoms	Defined by the presence of ≥1 delusions, characterized per specifiers listed below	Presence of single or multiple delusions that are persistent and may or may not be associated with hallucinations	▸ The presence of a delusion or set of related delusions ▸ Delusions vary in content but are stable within individuals, although they can evolve over time ▸ No hallucinations, disorganized thinking, or other evidence of a thought disorder ▸ Affect, speech, and behavior are typically unaffected
Psychosocial consequences	No marked impairment in psychosocial functioning, behavior, or obvious bizarre		
Exclusions	Having a history of meeting the criteria for schizophrenia Other medical condition Substance or medication including withdrawal Other mental illness	Personality disorder Psychosis, psychogenic reaction Schizophrenia	Other medical condition Substance or medication, including withdrawal Other mental illness
Symptom specifiers	**Erotomanic type**: delusion centered on the belief that another person is in love with the affected individual **Grandiose type**: delusions of grandeur prominent **Jealous type:** delusion centered on the belief that a partner is being unfaithful **Persecutory type:** delusions centered on the belief that one is being targeted		Positive symptoms Negative symptoms Depressive mood symptoms Manic mood symptoms Psychomotor symptoms Cognitive symptoms

	Somatic type: delusions focus on body and/or physical symptoms **Mixed type:** no predominant theme of delusions **Unspecified type** **With bizarre content:** if the content of delusions is felt to be wholly unrelated to reality or life experiences and/or completely impossible		
Course specifiers	**First episode, currently in acute episode** **First episode, currently in partial remission** (with partial remission refined as improvement in symptoms such that diagnostic criteria may no longer be fully met) **First episode, currently in full** remission (with full remission defined as lack of any symptoms) **Multiple episodes, currently in acute episode** **Multiple episodes, currently in partial remission** **Multiple episodes, currently in full remission** **Continuous** **Unspecified**		Currently symptomatic In partial remission In full remission

Table 16.
Brief Psychotic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Brief psychotic disorder	Acute and transient psychotic disorder	Acute and Transient psychotic disorder
Duration	Symptoms present 1 day to less than 1 month, followed by a return to baseline function		Occur suddenly and reach maximal severity within 2 weeks. Does not exceed 3 months.
Symptoms	Presence of: ▶ Delusions ▶ Hallucinations ▶ Disorganization of speech ▶ Disorganization of behavior and/or catatonia	Symptoms of schizophrenia, including: ▶ Thought echo ▶ Thought insertion or withdrawal ▶ Thought broadcasting ▶ Delusional perception ▶ Delusions or control, influence, or passivity ▶ Hallucinatory voices ▶ Disordered/disorganized thinking ▶ Negative symptoms May or may not be associated with polymorphic (unstable, frequently changing) delusions, hallucinations, and/or behavioral symptoms	Psychotic symptoms, which may include ▶ Delusions ▶ Hallucinations ▶ Disorganization of thought processes ▶ Perplexity or confusion ▶ Disturbances of affect and mood ▶ Catatonia-like disturbances
Required number of symptoms	≥1 of delusions, hallucinations, or disorganized speech must be present, with or without behavioral symptoms		
Psychosocial consequences			
Exclusions	Culturally sanctioned response/behavior Other medical condition Substance or medication, including withdrawal Other mental illness		Other medical condition Substance or medication, including withdrawal Other mental illness
Symptom specifiers	**With marked stressors** (presence of identifiable event triggering symptoms)	Acute polymorphic psychotic disorder without symptoms of schizophrenia	Positive symptoms Negative symptoms Depressive mood symptoms

	Without marked stressor **With catatonia** defined as the presence of ≥3 of the following: ▸ Reduced psychomotor activity/stupor ▸ Catalepsy (posture induced passively is held against gravity) ▸ Waxy flexibility (resistance to passive motion) ▸ Mutism ▸ Negativism ▸ Posturing ▸ Odd mannerisms ▸ Stereotypic behaviors ▸ Agitation ▸ Grimacing ▸ Echolalia (copying another's speech) ▸ Echopraxia (copying another's movements)	Acute polymorphic psychotic disorder with symptoms of schizophrenia **Acute schizophrenia-like psychotic disorder**–symptoms lasting less than 1 month, though if persistent, the diagnosis should be changed to schizophrenia **Other acute predominantly delusional psychotic disorders** **Other acute and transient psychotic disorder** **Acute and transient psychotic disorder, unspecified**	Manic mood symptoms Psychomotor symptoms Cognitive symptoms
Course specifiers	**With postpartum onset** (onset during pregnancy or within 4 weeks after giving birth)		First/multiple episode(s), currently symptomatic First/multiple episode(s), in partial remission First/multiple episode(s), in full remission First/multiple episode(s), unspecified

Table 17.
Schizophreniform Disorder/Acute and Transient Psychotic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Schizophreniform disorder	**Acute and transient psychotic disorder**	Acute and transient psychotic disorder
Duration	Presence of symptoms for ≥1 month but less than 6 months	Symptoms of a psychotic disorder present for less than 1 month on average. If symptoms persist, the diagnosis should be changed to schizophrenia	Occur suddenly and reach maximal severity within 2 weeks. Does not exceed 3 months.
Symptoms	Presence of: ▸ Delusions ▸ Hallucinations ▸ Disorganized speech ▸ Disorganized behavior and/or catatonia ▸ Negative symptoms (such as flattened affect, lack of motivation)	Symptoms of schizophrenia including: ▸ Thought echo ▸ Thought insertion or withdrawal ▸ Thought broadcasting ▸ Delusional perception ▸ Delusions or control, influence, or passivity ▸ Hallucinatory voices ▸ Disordered/disorganized thinking ▸ Negative symptoms May or may not be associated with polymorphic (unstable, frequently changing) delusions, hallucinations, and/or behavioral symptoms	Psychotic symptoms, which may include ▸ Delusions ▸ Hallucinations ▸ Disorganization of thought processes ▸ Perplexity or confusion ▸ Disturbances of affect and mood Catatonia-like disturbances
Required number of symptoms	≥2 of the above symptoms, among which ≥1 symptom must be delusions, hallucinations, or disorganized speech		
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness		Other medical condition Substance or medication, including withdrawal Other mental illness
Symptom specifiers	**With good prognostic features,** defined as the presence of ≥2 of the following: ▸ Psychotic symptoms occur within 4 weeks of initial behavioral changes		Positive symptoms Negative symptoms Depressive mood symptoms Manic mood symptoms Psychomotor symptoms Cognitive symptoms

	▶ Presence of confusion ▶ High presymptom functioning ▶ Absence of negative symptoms **Without good prognostic features** **With catatonia** defined as the presence of ≥3 of the following: ▶ Reduced psychomotor activity/stupor ▶ Catalepsy (posture induced passively is held against gravity) ▶ Waxy flexibility (resistance to passive motion) ▶ Mutism ▶ Negativism ▶ Posturing ▶ Odd mannerisms ▶ Stereotypic behaviors ▶ Agitation ▶ Grimacing ▶ Echolalia (copying another’s speech) ▶ Echopraxia (copying another’s movements)	
Course specifiers		First/multiple episode(s), currently symptomatic First/multiple episode(s), in partial remission First/multiple episode(s), in full remission First/multiple episode(s), unspecified

Table 18.
Schizophrenia

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Schizophrenia	Schizophrenia	Schizophrenia
Duration	Symptoms present continuously for ≥6 months		≥1 month
Symptoms	Presence of: ▶ Delusions ▶ Hallucinations ▶ Disorganized speech ▶ Disorganized behavior and/or catatonia ▶ Negative symptoms (such as flattened affect, lack of motivation)	Distortions in thinking and/or perception, in addition to negative changes in affect, frequently involving affective blunting. Symptoms may or may not be associated with cognitive dysfunction over time. Common symptoms include: ▶ Thought echo ▶ Thought insertion or withdrawal ▶ Thought broadcasting ▶ Delusional perception ▶ Delusions or control, influence, or passivity ▶ Hallucinatory voices ▶ Disordered/disorganized thinking ▶ Negative symptoms	Disturbance in multiple mental modalities, including ▶ Thinking (delusions, disorganized thought) ▶ Perception (hallucinations) ▶ Self-experience (of being externally controlled) ▶ Cognition (attention, verbal memory, social cognition) ▶ Volition (motivation) ▶ Affect (blunted) ▶ Behavior (bizarre, inappropriate, or purposeless) ▶ Catatonia may be present
Required number of symptoms	≥2 of the above symptoms, among which ≥1 symptom must be delusions, hallucinations, or disorganized speech		
Psychosocial consequences	Level of functioned decreased in ≥1 more major areas of function (e.g., work, interpersonal, self-care)		
Exclusions	Another medical condition Substance/Medication, including withdrawal Other mental illness (i.e., bipolar disorder, schizoaffective disorder if mood episode history is present)	Organic neurologic disease Schizoaffective disorder Epilepsy Psychoactive substances	Another medical condition Substance/medication, including withdrawal

Symptom specifiers	**With catatonia** defined as the presence of ≥3 of the following: ▶ Reduced psychomotor activity/stupor ▶ Catalepsy (posture induced passively is held against gravity) ▶ Waxy flexibility (resistance to passive motion) ▶ Mutism ▶ Negativism ▶ Posturing ▶ Odd mannerisms ▶ Stereotypic behaviors ▶ Agitation ▶ Grimacing ▶ Echolalia (copying another's speech) ▶ Echopraxia (copying another's movements)	**Paranoid schizophrenia** Hebephrenic schizophrenia prominent negative changes in affect, with inappropriate mood, social isolation, unpredictable behavior. Catatonic schizophrenia has prominent psychomotor changes associated with catatonia, such as posturing, odd mannerisms/affect, and stupor vs. agitation. **Undifferentiated schizophrenia** **Residual schizophrenia** chronic illness with evidence of cognitive changes as a result of long-standing disease **Simple schizophrenia** Slow progressive development of changes in behavior and functioning, with affective blunting developing often without clear preceding psychotic symptoms **Other schizophrenia** **Schizophrenia unspecified**	Positive symptoms Negative symptoms Depressive mood symptoms Manic mood symptoms Psychomotor symptoms Cognitive symptoms
Course specifiers	**First episode, currently in acute episode** First episode, currently in partial remission (with partial remission refined as improvement in symptoms such that diagnostic criteria may no longer be fully met) First episode, currently in full remission (with full remission defined as lack of any symptoms) Multiple episodes, currently in acute episode (at minimum		First/multiple episode(s), currently symptomatic First/multiple episode(s), in partial remission First/multiple episode(s), in full remission First/multiple episode(s), unspecified

has history of two episodes, separated by remission)
Multiple episodes, currently in partial remission
Multiple episodes, currently in full remission
Continuous
Unspecified

Table 19.
Schizoaffective Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Schizoaffective disorder	Schizoaffective disorders	Schizoaffective disorder
Duration	Mood episode symptoms must be present for more days than not during the total duration of the illness, though there must also be a period of ≥2 weeks during which delusions or hallucinations are present in the absence of mood episodes.		≥1 month
Symptoms	Presence of symptoms meeting criteria for a major depressive episode or manic episode while also exhibiting symptom criteria for Schizophrenia.	Episode presentation of symptoms of affective disturbance and schizophrenic symptoms that do not meet criteria for either schizophrenia or depressive/manic episodes.	Diagnostic requirements of schizophrenia and a manic, mixed, or moderate or severe depressive episode are met within the same episode of illness, either simultaneously or within a few days of each other.
Exclusions	Another medical condition Other mental illness A substance or medication, including withdrawal		Another medical condition Other mental illness A substance or medication, including withdrawal
Symptom specifiers	**Bipolar type:** manic episode present **Depressive type:** depressive episode present **With catatonia,** defined as the presence of ≥3 of the following: ▶ Reduced psychomotor activity/stupor ▶ Catalepsy (posture induced passively is held against gravity) ▶ Waxy flexibility (resistance to passive motion) ▶ Mutism	**Schizoaffective disorder manic type** Schizoaffective disorder, depressive type Schizoaffective disorder, mixed type Schizoaffective disorder, unspecified Other schizoaffective disorder	Positive symptoms Negative symptoms Depressive mood symptoms Manic mood symptoms Psychomotor symptoms Cognitive symptoms

	▶ Negativism ▶ Posturing ▶ Odd mannerisms ▶ Stereotypic behaviors ▶ Agitation ▶ Grimacing ▶ Echolalia (copying another's speech) ▶ Echopraxia (copying another's movements)
Course specifiers	**First episode, currently in acute episode** First episode, currently in partial remission (with partial remission refined as improvement in symptoms such that diagnostic criteria may no longer be fully met) First episode, currently in full remission (with full remission defined as lack of any symptoms) Multiple episodes, currently in acute episode (history of ≥2 episodes, separated by remission) Multiple episodes, currently in partial remission Multiple episodes, currently in full remission Continuous Unspecified

3. BIPOLAR AND RELATED DISORDERS

Table 20.
Bipolar 1 Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Bipolar 1 disorder	Bipolar affective disorder ***NOTE***: ICD-10 does not distinguish between Bipolar 1 and 2, requiring only a history of discrete episodes of mania, hypomania, and/or depression, with episodes demarcated by switches in mood/affect.	Bipolar 1 disorder
Duration	Manic episode: 1 week+ Hypomanic episode: 4 days+ Major depressive episode: 2 weeks+	Manic episode: 1 week+ Hypomanic episode: 4 days+ Major depressive episode: 2 weeks+	1 week+
Symptoms	**Manic or hypomanic episodes** ▶ abnormally ↑ or irritable mood (required) ▶ grandiose thoughts ▶ ↓ need for sleep ▶ pressured speech ▶ racing and expansive thoughts ▶ distractibility ▶ hyperactivity ▶ impulsivity/high-risk activities **Depressive episodes**—Similar to that for major depressive disorder	History of episodes of mania, hypomania, and/or depression, switches in mood/affect. **Mania** ▶ abnormally ↑ or irritable mood (required) ▶ Abnormally elevated or irritable mood ▶ ↑ activity ▶ ↑ talkativeness ▶ flight of ideas/racing thoughts ▶ social disinhibition ▶ ↓ need for sleep ▶ grandiose thoughts ▶ distractibility ▶ impulsivity/recklessness ▶ hypersexuality **Hypomania** ▶ abnormally ↑ mood (required) ▶ psychomotor agitation ▶ ↑ talkativeness ▶ Poor concentration/distractibility ▶ ↓ need for sleep ▶ hypersexuality ▶ impulsivity/ or ↑ spending ▶ over-familiarity **Depressive episode** ▶ Depressed mood ▶ Loss of interest or pleasure	**Manic episode** ▶ Extreme mood state (euphoria, irritability of expansiveness) ▶ Increased activity ▶ Talkativeness ▶ Flight of ideas ▶ Increased self-esteem ▶ Decreased need for sleep ▶ Distractibility ▶ Impulsivity ▶ Increased libido, sociability, or goal-directed activity **Mixed episode** Several prominent manic and several prominent depressive symptoms

		► Decreased energy ***Additional symptoms:*** ► Low self-esteem ► Excessive guilt or shame ► Recurrent thoughts of death or suicide ► Poor concentration ► Psychomotor changes ► Sleep disturbance ► Change in appetite and/or weight	
Required number of symptoms	≥1 manic episode Abnormally ↑ or irritable mood (required 3 of the other symptoms (4 if irritable mood)	**Bipolar affective disorder, current episode hypomanic** Hypomania (elevated mood and ≥3 symptoms History of a prior affective episode (manic, hypomanic, depressed, mixed) **Bipolar affective disorder, current episode manic** Mania (elevated or irritable mood and ≥ 3symptoms (4 if irritable mood) History of prior affective episodes (manic, hypomanic, depressed, mixed) **Bipolar Disorder, current episode mild/moderate/severe depression** Depressive episode (2/3 of the first 2 symptoms and 2 more of the additional symptoms) History of prior affective episodes (manic, hypomanic, depressed, mixed) **Bipolar disorder, current episode mixed** A mixture or rapid alternation of hypomanic, manic, and/or depressive symptoms (defined above) History of prior affective episodes (manic,	≥1 manic or mixed episode consisting of first 2 symptoms listed above, plus several of the other symptoms listed.

		hypomanic, depressed, mixed)	
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness	Psychoactive substance use Another mental disorder	Other medical condition Substance or medication, including withdrawal
Psychosocial consequences	***Manic episode:*** impaired functioning or needing hospitalization Hypomanic episode: no impairment or need for hospitalization Depressive episode: marked distress and/or psychosocial impairment		Impairment in ≥1 functional domain, or requiring intensive treatment (hospitalization), or includes hallucinations or delusion
Symptom specifiers	**Mild**—2 symptoms Moderate—3 symptoms Moderate–Severe—4–5 symptoms Severe—4–5 symptoms + motor agitation With mixed features ► Either a depressive or manic/hypomanic episode ► Additional symptoms of depressive or manic/hypomanic period (not full criteria) With rapid cycling ≥4 mood episodes in 1 year ≥2-month period of partial/full remission between episodes With melancholic features Similar to that for major depressive disorder With atypical features Similar to that for major depressive disorder With anxious distress:	**Current episode hypomanic** Current episode manic without psychotic symptoms Current episode manic with psychotic symptoms **Mood congruent** **Mood incongruent** **Current episode of depression** Current episode mixed Currently in remission—no symptoms. History of previous episodes. ***With somatic syndrome ≥4 of the following:*** ► ***Loss of interest or pleasure*** ► ***Lack of emotional reactivity*** ► ***Early morning awakening*** ► ***Depression gets worse in the mornings*** ► ***Psychomotor changes*** ► ***Loss of appetite*** ► ***Weight loss*** ► ***Loss of sexual drive***	**Current/Most recent episode:** Manic Hypomanic Depressive Mixed With/without psychotic symptoms With prominent anxiety symptoms With panic attacks With Seasonal pattern With rapid cycling Associated with pregnancy, childbirth, or the puerperium

	≥2 symptoms among the following: Feeling tense Restlessness Difficulty with concentration due to worrying XS fear without cause Fear of loss of control		
Course specifiers	**With peripartum onset:** episode occurs during pregnancy or within 4 weeks after delivery With seasonal pattern: pattern present for ≥2 years		
Severity specifiers		**For the current episode of depression** Mild: 4 symptoms Moderate: 6 symptoms, including ≥2 among loss of pleasure, depressed mood, and low energy Severe depression ≥8 symptoms, including all loss of pleasure, depressed mood, and low energy Without psychotic symptoms With psychotic symptoms Mood congruent Mood incongruent	**Mild** **Moderate** **Severe** **Unspecified severity**

Table 21.
Bipolar 2 Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Bipolar 2 disorder	Bipolar affective disorder **_*NOTE:_** ICD-10 does not distinguish between Bipolar 1 and 2, requiring only a history of discrete episodes of mania, hypomania, and/or depression, with episodes demarcated by switches in mood/affect.	Bipolar type II disorder
Duration	**Hypomanic episode:** lasting ≥4 days, with symptoms, present most of the day for most days **Major depressive episode**: symptoms lasting ≥2 weeks	Manic episode: lasting ≥1 week Hypomanic episode: lasting ≥4 days Major depressive episode: symptoms lasting ≥2 weeks	Several days
Symptoms	Hypomanic episodes involve abnormally elevated or irritable mood with: ▶ Grandiosity ▶ Decreased need for sleep ▶ Pressured speech ▶ Racing thoughts with expansiveness of thought ▶ Distractibility ▶ Goal-directed or non–goal-directed hyperactivity ▶ Engagement in high-risk activity or increased impulsivity Depressive episode involving depressed mood and/or decreased interest/pleasure with: ▶ Unintentional weight loss or change in appetite ▶ Disruption of sleep ▶ Psychomotor changes ▶ Loss of energy	History of discrete episodes of mania, hypomania, and/or depression, with episodes demarcated by switches in mood/affect. Episodes are defined as follows: **Mania:** abnormally elevated or irritable mood with ≥3 of the following (≥4 if mood irritable) ▶ Increased activity ▶ Increased talkativeness ▶ Flight of ideas/racing thoughts ▶ Social disinhibition ▶ Decreased need for sleep ▶ Grandiosity ▶ Distractibility ▶ Increased recklessness and impulsivity ▶ Hypersexuality **Hypomania:** abnormally elevated mood with ≥3	**Hypomanic Episode** Elevation of mood or irritability outside of the usual mood range Increased activity Talkativeness Flight of ideas Increased self-esteem Decreased need for sleep Distractibility Impulsivity Increased libido, sociability, or goal-directed activity Depressive episode ***See depressive disorders***

	▸ Difficulty with concentration and/or attention ▸ Excessive feelings of worthlessness and/or guilt ▸ Recurrent thoughts of death, including passive and/or active suicidal ideation	of the following: ▸ Psychomotor agitation ▸ Increased talkativeness ▸ Poor concentration or increased distractibility ▸ Decreased need for sleep ▸ Hypersexuality ▸ Impulsivity or increased spending ▸ Over-familiarity Depressive episode: 4 total symptoms from among the following: ≥2: ▸ Depressed mood ▸ Loss of interest or pleasure ▸ Decreased energy Additional symptoms: ▸ Low self-esteem ▸ Excessive guilt or shame ▸ Recurrent thoughts of death or suicide ▸ Poor concentration ▸ Psychomotor changes ▸ Sleep disturbance ▸ Change in appetite and/or weight	
Required number of symptoms	Lifetime history of a hypomanic episode involving elevated/irritable mood with ≥3 of the above symptoms (4 if mood irritable) Lifetime history of a depressive episode with ≥5 of the above symptoms, which must include ≥1 depressed mood or loss of pleasure	**Bipolar affective disorder, current episode hypomanic**—meets the above criteria for hypomania (elevated mood with ≥3 listed symptoms) and has a history of prior affective episodes (manic, hypomanic, depressed, mixed) **Bipolar affective disorder, current episode manic**—meets above criteria for mania (elevated or irritable mood with ≥3–4 listed symptoms) and	≥1 hypomanic episode ≥1 depressive episode

		has a history of prior affective episodes (manic, hypomanic, depressed, mixed) **Bipolar disorder, current episode mixed**—mixture or rapid alteration in hypomanic, manic, and/or depressive symptoms, with symptoms, present most of the time for ≥2 weeks, in addition to having a history of prior affective episodes (manic, hypomanic, depressed, mixed) **Bipolar disorder, current episode mild/moderate/severe depression**—current symptoms meet criteria for a depressive episode, in addition to having a history of prior affective episodes (manic, hypomanic, depressed, mixed)	
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness	Psychoactive substance use Another mental disorder	H/o manic episodes Other medical condition Effect of substance or medication
Psychosocial consequences	Hypomanic episode: NO marked impairment in functioning and NO hospitalization necessitated Depressive episode: marked distress and/or impairment in psychosocial functioning		Does not cause marked functional impairment
Symptom specifiers	**Current episode:** ***Depressed*** ***Hypomanic*** Additional specifiers to be added to the above:	**Current episode hypomanic** Current episode manic without psychotic symptoms	**Current/most recent episode** Hypomanic Depressive With/without psychotic symptoms

With anxious distress: including ≥2 symptoms among feeling tense, restlessness, difficulty with concentration due to worrying, excessive fear without an identifiable cause, fear of loss of control With mixed features—full criteria met for either depressive or manic/hypomanic episode, with additional symptoms of depressive or manic/hypomanic period without also meeting full criteria With rapid cycling—the presence of ≥4 mood episodes over the course of a 12-month period, with ≥2-month period of partial/full remission between mood episodes With melancholic features—involving loss of pleasure, reduced reactivity with ≥3 of the following: ▸ Depressed mood/despair ▸ Depressive symptoms worse in the morning ▸ Early morning awakening ▸ Psychomotor changes ▸ Loss of appetite/weight loss ▸ Excessive guilt **With atypical features:** during most days, an individual is experiencing mood reactivity with ≥2 symptoms of: ▸ Weight gain or increased appetite	Current episode manic with psychotic symptoms ▸ ***With mood congruent psychotic symptoms*** ▸ ***With mood incongruent psychotic symptoms*** **Current episode moderate or mild depression**—≥4 (mild) or 6 (moderate) symptoms present, including ≥2 among loss of pleasure, depressed mood, and low energy ***With somatic syndrome—≥4 of the following:*** ▸ ***Loss of interest or pleasure*** ▸ ***Lack of emotional reactivity*** ▸ ***Early morning awakening*** ▸ ***Depression gets worse in the mornings*** ▸ ***Psychomotor changes*** ▸ ***Loss of appetite*** ▸ ***Weight loss*** ▸ ***Loss of sexual drive*** ***Without somatic syndrome*** **Current episode severe depression without psychotic symptoms**—≥8 symptoms present, including all 3 of loss of pleasure, depressed mood, and low energy **Current episode severe depression with psychotic symptoms**—≥8 symptoms present, including all 3 of loss of pleasure, depressed mood, and	With prominent anxiety symptoms With panic attacks With seasonal pattern With rapid cycling Associated with pregnancy, childbirth, or the puerperium

	▸ Excessive sleeping ▸ Leaden paralysis ▸ A pattern of heightened interpersonal rejection sensitivity **With mood-congruent psychotic features**—mood-congruent delusions or hallucinations With mood-incongruent psychotic features—mood-incongruent delusions or hallucinations With catatonia—catatonic features present during most of the mood episode	low energy, occurring either ▸ ***With mood-congruent psychotic symptoms*** ▸ ***With mood incongruent psychotic symptoms*** **Current episode mixed** Currently in remission—does not currently meet criteria for an affective episode despite a prior history of a manic or hypomanic episode	
Course specifiers	**With peripartum onset**—full criteria for a mood episode are met during pregnancy or within 4 weeks of delivery With seasonal pattern (for ≥1 type of episode)—pattern present for ≥2 years In partial remission In full remission		
Severity specifiers	**Mild**—few symptoms in excess of minimum diagnostic criteria, with no to minimal impairment and/or distress **Moderate**—moderate symptomatology and impairment **Severe**—symptoms in marked excess of minimum diagnostic requirement, with marked distress and impairment in functioning	See the above criteria for mild, moderate, and severe depression	Mild Moderate Severe
Comments	**Note**: A diagnosis of		

Bipolar 2 cannot be made if there is a history of a manic episode, in which case a diagnosis of Bipolar 1 disorder would be made.

Table 22.
Cyclothymic Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Cyclothymic disorder	Cyclothymia	Cyclothymic disorder
Duration	Symptoms lasting ≥2 years (≥1 year in children), with depressive and hypomanic symptoms present for ≥half the time.	2-year period involving periods of depression and elevated mood, without ever meeting criteria for a depressive episode or manic episode.	≥2 years
Symptoms	Hypomanic episodes involve abnormally elevated or irritable mood with: ▶ Grandiosity ▶ Decreased need for sleep ▶ Pressured speech ▶ Racing thoughts with expansiveness of thought ▶ Distractibility ▶ Goal-directed or non–goal-directed hyperactivity ▶ Engagement in high-risk activity or increased impulsivity Depressive episode involving depressed mood and/or decreased interest/pleasure with: ▶ Unintentional weight loss or change in appetite ▶ Disruption of sleep ▶ Psychomotor changes ▶ Loss of energy ▶ Difficulty with concentration and/or attention ▶ Excessive feelings of worthlessness and/or guilt ▶ Recurrent thoughts of death, including passive and/or active suicidal ideation	Periods of depressed mood involving: ▶ Low energy ▶ Insomnia ▶ Low self-esteem ▶ Poor concentration ▶ Social withdrawal ▶ Loss of pleasure/enjoyment ▶ Reduced talkativeness ▶ Excessive pessimism Period of elevated mood involving: Increased energy ▶ Decreased need for sleep ▶ Inflated self-esteem ▶ Increased creativity ▶ More talkative ▶ More socially outgoing ▶ Hypersexuality and increased participation in pleasurable activities ▶ Grandiosity	Mood instability, with numerous hypomanic (see Bipolar type II disorder) and depressive periods (See depressive disorders). Children instead may show irritability. Hypomanic periods may or may not have been severe or long enough to meet criteria for hypomanic episode.
Required number	Symptoms of hypomania	≥3 symptoms during	

of symptoms	and depression present without ever meeting the full criteria for a depressive episode or manic episode	periods of mood elevation without meeting the full criteria for a manic episode ≥3 symptoms during periods of low mood without meeting the full criteria for a depressive episode	
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illnesses (Bipolar 1 or 2)	Bipolar affective disorder (though a history of bipolar affective disorder may be present)	Other medical condition Substance or medication, including withdrawal Other mental illness
Psychosocial consequences	Marked distress or impairment in areas of functioning		Marked distress or impairment in areas of functioning
Symptom specifiers	**With anxious distress:** including ≥2 symptoms among feeling tense, restlessness, difficulty with concentration due to worrying, excessive fear without an identifiable cause, fear of loss of control		
Course specifiers		**Early onset:** before 20s **Late onset:** onset between ages 30 and 50	
Severity specifiers	**Mild**—2 symptoms Moderate—3 symptoms Moderate–severe—4 or 5 symptoms Severe—4–5 symptoms with motor agitation		

4. DEPRESSIVE DISORDERS

Table 23.
Disruptive Mood Dysregulation Disorder/Other Persistent Mood [Affective] Disorders/Oppositional Defiant Disorder With Chronic Irritability-Anger, Unspecified

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Disruptive mood dysregulation disorder	Other persistent mood (affective) disorders	Oppositional defiant disorder with chronic irritability-anger, unspecified
Duration	Outbursts occurring ≥3 times per week for a duration of ≥12 months, during which there was no period >3 months during which all symptom criteria were not met.		
Symptoms	Recurrent verbal or physical outbursts out of proportion to the triggering event Not consistent with expected response per developmental level Mood between outbursts is irritable or mad most of the time		
Required number of symptoms	All of the above		
Exclusions	< age 6 > age 10 Other medical condition Substance or medication, including withdrawal Other mental illness Cannot co-occur with: ▸ Oppositional defiant disorder ▸ Intermittent explosive disorder ▸ Bipolar disorder		

Table 24.
Major Depressive Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Major depressive disorder	Major depressive episode	Major depressive disorder
Duration	2-week period	N/A	
Symptoms	Dysphoria/depressed mood Anhedonia Change in weight or appetite Change in sleep pattern Psychomotor disturbance: agitation or retardation Fatigue/decreased energy Depressive ruminations: worthlessness, guilt Poor concentration Recurrent thoughts of death, suicidal ideation, or a plan	Lowered mood Reduced energy Decreased activity Reduced capacity for enjoyment Reduced interest Reduced concentration Fatigue after even minimal effort Disturbed sleep/early morning awakening Disturbed appetite/weight loss Poor self-esteem Poor self-confidence Guilt or worthlessness Mood unreactive to circumstances Anhedonia Worse symptoms in the AM Psychomotor disturbance: agitation or retardation Loss of libido	**Affective cluster** ▸ Depressed mood ▸ Anhedonia **Cognitive-behavioral cluster** ▸ Poor concentration ▸ Low self-worth or inappropriate guilt ▸ Hopelessness ▸ Recurrent thoughts of death, suicidal ideation, or a plan **Neurovegetative cluster** ▸ Disrupted sleep ▸ Change in appetite ▸ Psychomotor agitation/retardation ▸ Fatigue/decreased energy
Required number of symptoms	5 (1 of these has to be symptom 1 or 2 listed above)	N/A	5 (≥1 from the affective cluster)
Psychosocial consequences	Distress or impaired functioning (social, occupational, or other significant areas)	Depends on severity	Significant impairment in ≥1 domain
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness History of: ▸ Manic episode ▸ Hypomanic episode	Adjustment disorder Conduct disorder Recurrent depressive disorder (which is considered a separate diagnosis)	Bereavement Mixed episode bipolar disorder Other medical consideration Effects of substance or medication
Symptom specifiers	**With anxious distress** ▸ 2+ symptoms of anxiety	Depressive reaction Psychogenic depression Reactive depression	Mild Moderate Severe

With mixed features

- 3+ manic/hypomanic symptoms occurring during the depressive episode (if occur independently, diagnose bipolar disorder)

With melancholic features

- Loss of pleasure or reactivity to pleasure
- 3+ of the following
- Severe depression/despair
- Mood worse in AM
- Early morning awakening
- Psychomotor disturbance
- Anorexia/weight loss
- Guilt

With atypical features

- Mood reactivity
- ≥2:
  - Increased appetite/weight
  - Hyposomnia
  - Leaden paralysis
  - Rejection sensitivity
  - With mood-congruent psychotic features
  - With mood-incongruent psychotic features

With psychotic features: symptoms occur only during a depressive episode. Also specify if delusions are mood congruent or incongruent.

With catatonia

- Must be present during most depressive episodes

With peripartum onset

- With seasonal pattern

Unspecified

With/without psychotic symptoms

With prominent anxiety symptoms

With panic attacks

Current depressive episode persistent

Current depressive episode with melancholia

With seasonal pattern

Associated with pregnancy, childbirth, or puerperium

	▶ Usually occurs during a specific season		
Course specifiers	**In partial remission:** full criteria no longer met **In full remission**: no symptoms of an episode for the past 2 months	**Recurrent depressive disorder** (coded as a separate disorder). Repeated episodes of the above symptoms. No mania.	**In partial remission** In full remission
Severity specifiers	**Mild:** minimum # symptoms **Moderate:** between mild and severe **Severe:** # of symptoms, the severity of symptoms, or dysfunction is much more than required for a diagnosis	**Mild** ▶ 2–3 symptoms ▶ Functions normally despite the distress **Moderate** ▶ 4+ symptoms. ▶ Difficulty with functioning **Severe** ▶ Several symptoms marked and distressing ▶ Loss of self-esteem/feels worthless and guilty ▶ Suicidal ideation/acts ▶ Somatic symptoms of depression **Severe with psychotic symptoms** ▶ As above but with psychosis Other ▶ Atypical depression ▶ Single episodes of “masked depression” Unspecified	

Table 25.
Persistent Depressive Disorder/Dythymia/Dysthymic Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Persistent depressive disorder	Dysthymia	Dysthymic disorder
Duration	Symptoms continuously present for ≥2 years No time during the affected period of no symptoms for >2 months		≥2 years
Symptoms	Depressed mood most of the time on a majority of days over a period of ≥2 years (NOTE: in children, irritability may be present, and duration must be for a period of ≥1 year) During the depressed period: ▶ Abnormal appetite (↑ or ↓) ▶ Abnormal sleep (↑ or ↓) ▶ ↓ energy ▶ ↓ self-esteem ▶ ↓ concentration or ↑ indecisiveness ▶ Hopelessness	Chronically depressed mood that does not meet criteria for a depressive episode, though criteria may have been met in the past.	Persistent depressed mood Additional symptoms of depression. May include: ▶ Anhedonia or decreased interest ▶ Poor concentration ▶ Low self-worth or inappropriate guilt ▶ Hopelessness ▶ Disturbed sleep ▶ Change in appetite ▶ Fatigue or low energy
Required number of symptoms	≥2 bulleted symptoms		
Psychosocial consequences	Marked distress and/or functional impairment		Marked distress and/or functional impairment
Exclusions	This cannot occur with a history of bipolar disorder Other medical condition Substance or medication, including withdrawal Other mental illness	Result of: ▶ Anxiety ▶ Depression ▶ Bereavement ▶ Schizophrenia	A depressive episode in the first 2 years of the disorder History of manic, mixed, or hypomanic episodes Other medical condition Substance or medication, including withdrawal
Symptom specifiers	**With pure dysthymic syndrome:** criteria for the depressive episode not met in the last 2 years		

With persistent major depressive episode: has met diagnostic criteria for a depressive episode for an entire 2-year period

With intermittent major depressive episode, with current episode: though may currently meet criteria for major depressive disorder, has had a period of ≥8 weeks during the prior 2-year period during which symptoms were below the diagnostic threshold for a depressive episode.

With intermittent major depressive episode, without current episode: does not currently meet criteria for a depressive episode, though has experienced ≥1 depressive episode over the course of the prior 2 years.

With anxious distress: including ≥2 symptoms among feeling tense, restlessness, difficulty with concentration due to worrying, excessive fear without an identifiable cause, fear of loss of control.

With mixed features—full criteria met for either depressive or manic/hypomanic episode, with additional symptoms of depressive or manic/hypomanic period without also meeting full criteria.

	With melancholic features—involving loss of pleasure, reduced reactivity with ≥3 of the following: ► Depressed mood/despair ► Depressive symptoms worse in the morning ► Early morning awakening ► Psychomotor changes ► Loss of appetite/weight loss ► Excessive guilt
	With atypical features: during most days, an individual is experiencing mood reactivity with ≥2 symptoms: ► Weight gain or increased appetite ► Excessive sleeping ► Leaden paralysis ► A pattern of heightened interpersonal rejection sensitivity
	With mood-congruent psychotic features – mood-congruent delusions or hallucinations
	With mood-incongruent psychotic features– mood-incongruent delusions or hallucinations
Course specifiers	**With peripartum onset**—full criteria for a mood episode are met during pregnancy or within 4 weeks of delivery
Severity specifiers	**Mild**—few symptoms in excess of minimum diagnostic criteria, with no to minimal

impairment and/or distress

Moderate—moderate symptomatology and impairment

Severe—symptoms in marked excess of minimum diagnostic requirement, with marked distress and impairment in functioning

Table 26.
Premenstrual Dysphoric Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Premenstrual dysphoric disorder		Premenstrual dysphoric disorder
Duration	Symptoms present in the week leading up to menses and improve with the onset of menses while resolving or nearly resolving in the week following menses. Symptoms should be present over the course of 2 menstrual cycles.		
Symptoms	Mood symptoms: ▶ Mood swings ▶ Irritability ▶ Depressed mood or low self-esteem ▶ Anxiety Other symptoms: ▶ Decreased interest in normally pleasurable activities ▶ Reduced concentration ▶ Fatigue ▶ Change in appetite ▶ Change in sleep (increased or decreased) ▶ Feeling of being overwhelmed ▶ Physical symptoms (bloating, musculoskeletal pain, breast discomfort)		Symptoms associated with most menstrual cyclesaffective symptoms ▶ Mood lability ▶ Irritability ▶ Depression ▶ Anxiety Somatic or cognitive symptoms: ▶ Lethargy ▶ Joint pain ▶ Overeating ▶ Hypersomnia ▶ Breast tenderness ▶ Extremity swelling ▶ Difficulty concentrating ▶ Forgetfulness
Required number of symptoms	≥1 Mood symptoms ≥1 Other symptom		≥ Affective symptom
Psychosocial consequences	Distress or functional impairment		Distress or functional impairment
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness		Other medical condition Substance or medication, including withdrawal Other mental illness

5. ANXIETY DISORDERS

Table 27.
Separation Anxiety Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Separation anxiety disorder	Separation anxiety disorder of childhood	Separation anxiety disorder
Duration	Symptoms persist over ≥4 weeks in children or ≥6 months in adults		≥ Several months
Symptoms	Recurrent distress on separation or anticipated separation from the attachment figure Worry of losing attachment figure or of their being harmed Worry about unexpected events that will result in forced separation from the attachment figure Hesitance to leave home or be away from the attachment figure Fear of being alone in a setting without an attachment figure Difficulty sleeping without being near attachment figure Nightmares related to fear of separation Physical symptoms occurring during separation or anticipation of separation	Fear of separation causes anxiety Anxiety arises during early childhood Severity is out of proportion and of longer duration than would be expected by normal developmental/age standards	Marked/ excessive fear/anxiety about separation from an attachment figure Symptoms vary by developmental level but may include: Persistent thoughts of being separated due to some harm/unexpected event Reluctance/refusal to go to school or work Excess distress related to a separation from an attachment figure Recurrent nightmares about separation Physical symptoms associated with separation (gastrointestinal, headaches)
Required number of symptoms	≥3 of the symptoms above meeting the required duration		
Psychosocial consequences	Distress or psychosocial impairment	Impaired functioning	Distress or psychosocial impairment
Exclusions	Another mental disorder		Another mental disorder
Comments		Note: classified under (Emotional disorders with onset specific to childhood)	

Table 28.
Selective Mutism

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Selective mutism	Elective mutism	Selective mutism
Duration	≥1 month (not exclusively during the first month of school)		≥1 month (not exclusively during the first month of school)
Symptoms	Persistent lack of speech in particular social situations despite being able to speak in other situations.	Presence of selectively speaking related to specific emotions, resulting in a child that has previously demonstrated the ability to speak not speaking in particular social situations. It may be associated with other symptoms of anxiety, social withdrawal, and sensitivity	Selectivity in speaking with language competence in some situations but not others.
Psychosocial consequences	Psychosocial impairment		Psychosocial impairment
Exclusions	Another mental disorder Communication disorder Lack of proficiency with the spoken language in a given situation	Pervasive developmental disorders Developmental disorders of speech and language Transient mutism as part of separation anxiety in young children	Another mental disorder
Comments		Note: classified as a disorder of social functioning with onset specific to childhood and adolescence	

Table 29.
Specific Phobia

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Specific phobia	Specific (isolated) phobias	Specific phobia
Duration	Persistent and lasting ≥6 months		Persistent and lasting ≥ several months
Symptoms	Fear and/or anxiety related to particular objects or situations Exposure to that object or situation often results in immediate fear and/or anxiety Avoidance of the feared object or situation Fear/anxiety response is out of proportion to the given context	Phobias are restricted to highly specific situations, objects, or activities. Exposure to such situations, objects, or activities can result in panic.	Marked and excessive fear due to the occurrence or anticipation of a specific object or situation Feared object/situation is avoided or endured with intense anxiety
Required number of symptoms	All of the above		
Psychosocial consequences	Distress or psychosocial impairment		Distress or psychosocial impairment
Exclusions	Other mental disorder		Other mental disorder
Symptom specifiers	Animals Natural environment Blood-injection-injury Fear of blood Fear of injections and transfusions Fear of other medical care Fear of injury Situational Other		With Panic attack
Comments		Other phobic anxiety disorder Phobic anxiety disorder, unspecified	

Table 30.
Social Anxiety Disorder/Social Phobias

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Social anxiety disorder (social phobia)	Social phobias	Social anxiety disorder
Duration	Persistent and lasting typically ≥6 months		Persistent and lasting ≥several months
Symptoms	Anxiety related to social situations, given the fear of being judged or scrutinized by others Fear of allowing anxiety to show and be noticed by others, be perceived negatively, or will lead to embarrassment or rejection Avoidance of feared social situations Anxiety and fear are out of proportion to the social context	Fear of being judged or scrutinized by other people Fear of judgment or embarrassment leads to avoidance of social situations It can be associated with low self-esteem Panic attacks may develop	Anxiety occurs in ≥1 social interaction or while performing Fear or concern of being negatively evaluated by others The feared situation is avoided or endured with intense anxiety
Required number of symptoms	All of the above		
Psychosocial consequences	Marked distress and/or impairment		Marked distress and/or impairment
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness		Other mental illness
Symptom specifiers	**Performance only** (anxiety related specifically to publicly performing or speaking)		

Table 31.
Panic Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Panic disorder	Panic disorder (episodic paroxysmal anxiety)	Panic disorder
Duration	≥1 panic attack must be followed by ≥1 month of worry symptoms as defined below		
Symptoms	Recurrent and unpredictable panic attacks, which can involve: ▶ Palpitations ▶ Sweating ▶ Tremulousness ▶ Feeling short of breath ▶ Chest discomfort ▶ Nausea or GI discomfort ▶ Dizziness ▶ Chills or feeling flushed ▶ Numbness or tingling ▶ Derealization or depersonalization ▶ Fear of losing control ▶ Fear of impending death Persistent symptoms between attacks, including: ▶ Persistent fear of having another attack and of its consequences ▶ Maladaptive behaviors to avoid situations perceived to be related to the development of a panic attack	Presence of recurrent “attacks” of severe anxiety and panic Panic attacks are not associated with a particular situation or setting and are thus unpredictable Prominent physiologic symptoms are present, such as chest pain, palpitations, difficulty breathing, sweating, dizziness Additional symptoms may include depersonalization, derealization, fear of losing control, fear of dying	Recurrent panic attacks ≥some of which are unexpected. Symptoms may include (but not be limited to): ▶ Palpitations ▶ Sweating ▶ Tremulousness ▶ Feeling short of breath ▶ Chest discomfort ▶ Nausea or GI discomfort ▶ Dizziness ▶ Chills or feeling flushed ▶ Numbness or tingling ▶ Derealization or depersonalization ▶ Fear of losing control ▶ Fear of impending death Attacks are followed by persistent concern or worry, typically for several weeks
Required number of symptoms	≥4 more symptoms of a panic attack present during a discrete, abrupt, and unpredictable episode, with ≥1 panic episode followed by >1 month of fear of the next		

	attack, avoidance, or both.		
Psychosocial consequences			Distress or psychosocial impairment
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness	Result of: ▶ Other mental illnesses presenting with panic-like symptoms	Other medical condition Substance or medication, including withdrawal Other mental illness
Comments	A separate diagnosis for “Panic Attack Specifier” is present and can be used for individuals experiencing discrete panic attacks (as defined by the above symptoms) occurring without additional criteria for panic disorder and occurring in the context of another psychiatric disorder		

Table 32.
Agoraphobia

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Agoraphobia	Agoraphobia	Agoraphobia
Duration	Persistent and lasting ≥6 months		Persistent and lasting ≥ several months
Symptoms	Fear or anxiety arising from: ▶ Public transportation ▶ Open spaces ▶ Confined spaces ▶ Being in a line or in a crowd ▶ Being alone outside of the home Avoidance of the above situations due to fear of developing panic-related symptoms or requiring companionship to endure said feared situations Fear and avoidance are out of proportion to the actual threat of the avoided situation	Fear of leaving home, going to public and/or crowded places or traveling alone Frequently associated with panic disorders Presence of a prominent pattern of avoidance of anxiety-provoking situations	Marked and excessive fear or anxiety occurring in (or in anticipation of) situations where escape would be difficult Fear of negative consequences of such situations (i.e., panic) Situations avoided, endured with anxiety, or only attempted under specific circumstances, such as with a companion
Psychosocial consequences	Distress or psychosocial impairment		Distress or psychosocial impairment
Exclusions	Other medical condition Other mental illness		Other mental illness
Comments	Diagnosis of agoraphobia can be made without the presence of a panic disorder.		

Table 33.
Generalized Anxiety Disorder

	DSM-5/DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Generalized anxiety disorder	Generalized anxiety disorder	Generalized anxiety disorder
Duration	≥6 months, more days than not		Persists for several months, more days than not
Symptoms	Excessive anxiety or worry about a wide range of situations Difficulty controlling or managing worry Symptoms of anxiety/worry, including: ▶ Restlessness ▶ Fatigue ▶ Poor concentration ▶ Irritability ▶ Muscle tension ▶ Sleep disturbance	Persistent and generalized anxiety Anxiety not associated with a particular object, event, or situation Predominant symptoms may include worry, shaking, muscle tension, sweating, lightheadedness, palpitations, and GI symptoms	Free-floating anxiety or excessive worry about negative events Anxiety is accompanied by symptoms such as: ▶ Motor restlessness, muscle tension ▶ Autonomic overactivity ▶ Feeling nervous, restless, or on edge ▶ Difficulty concentrating ▶ Irritability ▶ Insomnia
Required number of symptoms	Both excessive worry and difficulty controlling worry must be present, in addition to ≥3 of the associated symptoms of anxiety/worry		
Psychosocial consequences	Distress or psychosocial impairment		Distress or psychosocial impairment
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness		Other medical condition Substance or medication, including withdrawal Other mental illness

6. OBSESSIVE-COMPULSIVE AND RELATED DISORDERS

Table 34.
Obsessive-Compulsive Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Obsessive-compulsive disorder	Obsessive-compulsive disorder	Obsessive-compulsive disorder
Duration	Persistent		Persistent
Symptoms	Obsessions (intrusive thoughts that accompany behaviors and that individuals may attempt to ignore or counteract through action) Compulsions (repetitive actions, commonly driven by an obsessive thought, performed to relieve anxiety or fear)	Recurrent obsessional thoughts and/or compulsive acts ▸ Obsessions: ideas, images, or impulses occurring recurrently ▸ Compulsions: repeated, stereotyped behaviors meant to neutralize a thought/anxiety or prevent a perceived adverse event Attempts at resisting thoughts and behaviors are frequently unsuccessful and cause worsening anxiety	Obsessions: repetitive/persistent thoughts/images/impulses, experienced as intrusive and unwanted, associated with anxiety Compulsions: repetitive behaviors/rituals in response to obsessions
Required number of symptoms	Obsessive thoughts, compulsions, or both	Presence of obsessions, compulsions, or both	
Psychosocial consequences	Symptoms and behaviors consume ≥1 hour per day or cause distress or psychosocial impairment		Symptoms and behaviors consume ≥1 hour per day or cause distress or psychosocial impairment
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness	Obsessive-compulsive personality disorder	Other medical condition Substance or medication, including withdrawal
Symptom specifiers	Tic related: current or prior tic disorder With good or fair insight With poor insight With absent insight and/or delusional beliefs	Predominantly obsessional thoughts or ruminations Predominantly compulsive acts (obsessional rituals) Mixed obsessional thoughts and acts	Fair to good insight Poor to absent insight

Table 35.
Body Dysmorphic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Body dysmorphic disorder	Body dysmorphic disorder	Body dysmorphic disorder
Symptoms	Preoccupation with physical appearance and subjective flaws Presence of repetitive behaviors at some point during the disorder ▸ Checking ▸ Grooming ▸ Skin picking ▸ Recurrent thoughts/perseveration on comparing physical appearance to that of others	Excessive preoccupation with image or appearance	Persistent preoccupation with ≥1 perceived defects or flaws in appearance Excessive self-consciousness about the perceived defect(s)Accompanied by any of the following: ▸ Repetitive/excessive behaviors (repeatedly examining) ▸ Excessive attempts to hide or alter the defect ▸ Avoiding social or other situations
Required number of symptoms	Both of the above causing significant impairment and/or distress and excluding other causes of symptoms		
Psychosocial consequences	Distress or psychosocial impairment	Distress or psychosocial impairment	
Exclusions	An eating disorder (if the primary focus is body fat or weight)		Other medical illness Substance
Symptom specifiers	With muscle dysmorphia: preoccupation with perceived low muscle mass or small body build With good or fair insight With poor insight With absent insight and/or delusional beliefs		Fair to good insight Poor to absent insight

Table 36.
Hoarding Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Hoarding disorder	Hoarding disorder	Hoarding disorder
Symptoms	Excessive attachment to possessions Distress related to being separated from items Excessive accumulation of possessions Accumulation results in significant distress, impairment, and/or safety/health compromise	Difficulty parting with objects due to perceived need to save possessions Distress and functional impairment associated with being separated from possessions	Accumulation of possessions, resulting in unusable or unsafe living conditions due to ▶ Repetitive urges/behaviors to amass items ▶ Difficulty discarding possessions
Required number of symptoms	All of the above		
Psychosocial consequences	Symptoms and behaviors cause significant distress or impairment	Symptoms and behaviors cause significant distress or impairment	Symptoms and behaviors cause significant distress or impairment
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness		
Symptom specifiers	With excessive acquisition With good or fair insight With poor insight With absent insight and/or delusional beliefs		Fair to good insight Poor to absent insight
Severity specifiers	With or without insight (per above)		

Table 37.
Trichotillomania/Body-Focused Repetitive Behavior Disorders

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Trichotillomania (hair-pulling disorder)	Trichotillomania	Body-focused repetitive behavior disorders
Symptoms	Recurrent hair pulling causing hair loss Repeated attempts to change/end behaviors	Presence of noticeable hair loss due to recurrent hair pulling Hair-pulling behavior preceded by increased anxiety that is relieved by hair-pulling	Recurrent and habitual actions directed at the integument (e.g., hair-pulling, skin-picking, lip-biting) Typically accompanied by unsuccessful attempts to decrease or stop the behaviors
Required number of symptoms	All of the above		
Psychosocial consequences	Distress or psychosocial impairment		Distress or psychosocial impairment
Exclusions	Other medical condition Substance or medication, including withdrawal	Pre-existing inflammation of the skin Response to delusion or hallucination Stereotyped movement disorder	Cultural behaviors (i.e., self-flagellation as part of religious ceremonies)

Table 38.
Excoriation (Skin Picking) Disorder/Body-Focused Repetitive Behavior Disorders

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Excoriation (skin picking) disorder	Excoriation (skin picking) disorder	Body-focused repetitive behavior disorders
Symptoms	Recurrent skin picking causing lesions to the skin Ongoing skin picking despite repeated attempts to change/end behaviors Actions cause distress and/or impaired functioning	Included under obsessive-compulsive disorders	Recurrent and habitual actions directed at the integument (e.g., hair-pulling, skin-picking, lip-biting). Typically accompanied by unsuccessful attempts to decrease or stop the behaviors
Required number of symptoms	All of the above		
Psychosocial consequences	Distress or psychosocial impairment		Distress or psychosocial impairment
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness	Factitious dermatitis	Cultural behaviors (i.e., self-flagellation as part of religious ceremonies)

7. TRAUMA RELATED DISORDERS

Table 39.
Reactive Attachment Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Reactive attachment disorder	Reactive attachment disorder of childhood	Reactive attachment disorder
Symptoms	Behavioral pattern characterized by emotional withdrawal ▶ Not seeking or not responding to emotional comforting A pattern of social/emotional disturbance ▶ Lack of mood reactivity or positive affective response to stimuli ▶ Inappropriate mood lability/irritability/sadness History of exposure to severely insufficient caregiving ▶ Severe neglect ▶ Unstable caregiving environment with frequent changes in caregivers ▶ Being raised in unusual care settings Evidence for the disorder after the developmental age of 9 and before age 5	A pattern of abnormal social relationships involving emotional disturbance and behavioral changes ▶ i.e., fear, hypervigilance, poor socialization, aggression toward self and others, delayed growth in some instances Symptoms present before 5 years of age Likely occur as a direct result of neglect, abuse, or maltreatment during rearing	History of grossly insufficient care ▶ Disregard for the child's physical and emotional needs ▶ Frequent changes in primary caregivers ▶ Rearing in unusual settings ▶ Maltreatment Abnormal attachment behaviors ▶ Minimal seeking of comfort when distressed ▶ Minimal response to comfort when offered Insufficient care is presumed to be responsible for the child's behaviors Evidence for the disorder after the developmental age of 9 and before age 5
Required number of symptoms	All of the above categories, with behavioral symptoms, felt to be the direct result of exposure to inadequate caregiving or rearing environment		
Psychosocial consequences	Significant disturbance of behavior		
Exclusions	Autism spectrum disorder	Asperger syndrome Disinhibited attachment disorder of childhood Maltreatment syndromes Normal variation in the pattern of selective attachment Sexual or physical abuse in childhood,	Autism spectrum disorder Not confined to one relationship

		resulting in psychosocial problems
Symptom specifiers		Specifiers for: Failure to thrive [R62.51] Growth retardation
Course specifiers	**Persistent** (>12 months)	
Severity specifiers	**Severe:** all symptom criteria met, with symptoms presenting at a high level of severity as well	

Table 40.
Disinhibited Social Engagement Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Disinhibited social engagement disorder	Disinhibited attachment disorder of childhood	Disinhibited social engagement disorder
Symptoms	Childhood pattern of approaching unfamiliar adults ▶ Lack of inhibition in approaching unfamiliar adults ▶ Overly familiar behavior toward unfamiliar adults ▶ Reduced frequency of checking in with known adult/caregiver figure ▶ Minimal or no hesitation to venture forth with an unfamiliar adult History of exposure to insufficient care ▶ History of neglectful rearing environment ▶ A pattern of instability and frequent changes in caregiver ▶ Raised in an unusual setting for child rearing The developmental age of ≥9 months and before age 5 years	A pattern of nonselective attachment, attention-seeking, indiscriminate behaviors with peers and strangers Abnormal social interaction patterns arise before the age of 5 years It may or may not be associated with emotional or behavioral disturbance	History of grossly insufficient care ▶ Disregard for the child’s physical and emotional needs ▶ Frequent changes in primary caregivers ▶ Rearing in unusual settings ▶ Maltreatment Abnormal attachment behaviors ▶ Overly familiar behaviors with adult strangers ▶ Decreased checking back with caregiver ▶ Willing to go off with unfamiliar adults with little hesitation Evidence for the disorder after age 1 or developmental age of 9 months and before age 5
Required number of symptoms	Two symptoms of disinhibited behavior with an unfamiliar adult, in addition to a history of exposure to an abnormal child-rearing environment as above, are related to the development of abnormal behavior		
Psychosocial consequences	Significant disturbance of behavior resulting in impaired safety and/or functioning		
Exclusions	Symptoms limited to	Asperger syndrome	Asperger syndrome

	impulsivity without socially disinhibited behavior	Hospitalism in children Hyperkinetic disorders Reactive attachment disorder of childhood	Adjustment disorder Attention-deficit hyperactivity disorder Reactive attachment disorder of childhood
Course specifiers	**Persistent** Present for ≥12 months		
Severity specifiers	**Severe:** child exhibiting all symptoms, with all symptoms at relatively high levels		

Table 41.
Post-Traumatic Stress Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Post-traumatic stress disorder	Post-traumatic stress disorder	Post-traumatic stress disorder
Duration	>1 month	Symptoms arise in weeks to months following the traumatic event	
Symptoms	History of exposure to (directly experiencing, repeated exposure witnessing in person, learning of occurrence in close acquaintance) actual threatened death, severe injury, or sexual trauma Intrusive symptoms ▶ Involuntary intrusive memories ▶ In children <6 years may see a re-enactment of the event through play ▶ Recurrent nightmares/dreams of the event ▶ In children <6 years, frightening dreams without identifiable content may be present ▶ Dissociative responses or reliving of prior experience (i.e., flashbacks) ▶ In children <6 years may see a re-enactment of the event through play ▶ Psychological distress related to exposure to stimuli that are reminders of prior trauma	Symptoms arise as a delayed or prolonged response to a single or recurrent stressful experience that is life-threatening or catastrophic in severity The traumatic event would cause distress in most individuals Symptoms may include ▶ Flashbacks ▶ Dreams/nightmares ▶ Emotional blunting and subjective numbness ▶ Social withdrawal/detachment ▶ Anhedonia ▶ Avoidance ▶ Hyperarousal/hypervigilance ▶ Sleep disturbance May or may not be associated with co-occurring anxiety and/or depression	Exposure to an extremely threatening or horrifying event. Following the event develops symptoms in all three of the following categories: ▶ Re-experiencing the trauma ▶ Avoiding reminders of the trauma ▶ Persistent perception of heightened threat (e.g., hypervigilance)

	▸ Presence of physiologic response to stimuli that are reminders of prior trauma Avoidance of stimuli associated with prior experience of trauma ▸ Avoidance of memories related to trauma ▸ Avoidance of external reminders of the trauma Negative mood or cognitions related to trauma ▸ Impairment in memories related to the event ▸ Negative perceptions of self and others ▸ Cognitive distortions related to the event ▸ Excessive guilt, anger, or fear ▸ Diminished interest and social withdrawal ▸ Subjective detachment from others ▸ Difficulty experiencing positive feelings in response to previously pleasurable stimuli Altered level of arousal ▸ Irritability and/or anger ▸ Risk-taking ▸ Hypervigilance ▸ Increased startle response ▸ Difficulties with concentration ▸ Sleep disturbances	
Required number of symptoms	In addition to a history of exposure to	Any of the above

	trauma, they must have ▸ ≥1 symptom of intrusion ▸ ≥1 symptom of avoidance ▸ ≥2 symptoms of negative mood/cognition ▸ ≥2 symptoms of arousal alterations,		
Psychosocial consequences	Marked distress and impairment in functioning		Impairment in functioning
Exclusions	Exposure through media, electronics, movies, or photo Related to substance use Related to another medical condition		Acute stress reaction Complex post-traumatic stress disorder
Symptom specifiers	**With dissociative symptoms:** ▸ **Depersonalization:** perception of feeling outside one's own body ▸ **Derealization:** perception of the surrounding environment being unreal or distorted		
Course specifiers	**With delayed expression** ▸ All diagnostic criteria are not met until ≥6 months after an initial traumatic event		

Table 42.
Acute Stress Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Acute stress disorder	Acute stress reaction	Acute stress disorder
Duration	3 days to <1 month following exposure to trauma	Symptoms arise transiently in response to emotional or physical stress and are usually resolved within hours or days	Begin hours to days after stressor, end within a few days of removal of stressor, or if stressor is ongoing, reduced within 1 month.
Symptoms	Exposure to actual or threatened death/injury/sexual violence through ≥1 of the following ways: ▶ Direct experience ▶ Personally witnessing events occurring to others ▶ Learning of events happening to close family or friend ▶ Experiencing repeated/extreme exposure to aversive details of a trauma Intrusive symptoms ▶ Recurrent memories of the trauma ▶ Recurrent nightmares ▶ Dissociative reactions (e.g., flashbacks) ▶ Intense/prolonged distress or physiologic reactions in response to cues of the event Negative mood ▶ Inability to experience positive emotions Dissociate symptoms ▶ Altered sense of reality ▶ Dissociate amnesia regarding an event Avoidance symptoms ▶ Efforts to avoid thinking about the trauma ▶ Efforts to avoid reminders of the trauma	Cognitive “daze” Narrowed attention Difficulties with comprehension Disorientation Autonomic symptoms of panic May be followed by the further withdrawal from the situation or possible agitation/excitability May have partial or complete amnesia related to the event	Exposure to an extremely threatening or horrifying event Response to the stressor that is normal given the severity

	Arousal symptoms ► Insomnia ► Irritability ► Hypervigilance ► Decreased concentration ► Increased startle response	
Required number of symptoms	Nine symptoms from among the above five categories	
Psychosocial consequences	Marked distress and impairment in functioning	
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness	Post-traumatic stress disorder

Table 43.
Adjustment Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Adjustment disorder	Adjustment disorders	Adjustment disorder
Duration	Occurring within 3 months of an acute stressor and resolving within 6 months of the resolution of the stressor		Within 6 months of the resolution of the stressor
Symptoms	Emotional or behavioral changes Marked distress/impairment that is felt to be out of proportion to the stressor itself	Subjective distress/emotional disturbance Arises during the period of adaptation to a change or stress Symptoms of depressed mood or anxiety may arise, and conduct disturbance may be noted in adolescents	A maladaptive reaction to an identifiable psychosocial stressor, consisting of preoccupation with the stressor or its consequences
Required number of symptoms	All of the above		
Psychosocial consequences	Marked distress/functional impairment	Often result in impairment in social functioning	Functional impairment
Exclusions	Exacerbation of existing mental illness Normal bereavement Other psychiatric illness		Separation anxiety disorder of childhood Recurrent depressive disorder Single-episode depressive disorder Prolonged grief disorder Uncomplicated bereavement Burnout Acute stress reaction
Symptom specifiers	**With depressed mood:** ► Predominant low mood, hopelessness **With anxiety:** ► Predominant anxiety, worry **With mixed anxiety and depressed mood:** ► Both low mood and anxiety present **With mixed disturbance of emotions and**		

conduct:

- Mood and conduct disturbance present

Unspecified

Table 44.
Prolonged Grief Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Prolonged grief disorder	Adjustment disorder, grief reaction (see Adjustment disorder)	Prolonged grief disorder
Duration	Within 12 months (6 for child or adolescents) after a death of a person close to the individual. Symptoms last ≥1 month.		An atypically long time following a loss and ≥6 months
Symptoms	Persistent grief ▸ Longing for the deceased ▸ Preoccupation with thoughts of the deceased Accompanying symptoms relating to or resulting from the death: ▸ Identity disruption ▸ Disbelief about the death ▸ Avoiding reminders of the loss ▸ Intense emotional pain ▸ Difficulty resuming relationships/activities ▸ Emotional numbness ▸ Feeling life is meaningless ▸ Intense loneliness		Bereavement following the death of a close person Persistent/pervasive grief response
Required number of symptoms	Persistent grief: one or both Accompanying symptoms: ≥3		
Psychosocial consequences	Marked distress/functional impairment		Marked distress/functional impairment
Exclusions	Normal grief Other medical disorder Other mental disorder Substance use		

8. DISSOCIATIVE DISORDERS

Table 45.
Dissociative Identity Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Dissociative identity disorder	Dissociative (conversion) disorder, unspecified	Dissociative identity disorder
Symptoms	Disrupted sense of identity, which is related to the presence of ≥2 personality states, with associated changes in the sense of self-control, affect, behavior, memory, perception, or sensory-motor function Gaps in memory related to past events or personal information	Disruption of identity characterized by the presence of ≥2 distinct personality states ≥2 personalities recurrently take executive control of the individual's consciousness and functioning Changes in personality state are accompanied by alterations in sensation, perception, affect, cognition, memory, motor control, and behavior.	
Required number of symptoms	All of the above Symptoms part of an accepted belief system		
Exclusions	Normal forgetting Other medical condition Substance or medication, including withdrawal Fantasy play in children	Other mental disorder Substance or medication Other medical disorder	
Psychosocial consequences	Marked distress and/or impairment	Functional impairment	
Comments	Trance and possession disorders: temporary loss of the sense of personal identity and full awareness of the surroundings that are outside of culture-bound norms.		

Table 46.
Dissociative Amnesia

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Dissociative amnesia	Dissociative amnesia Dissociative fugue	Dissociative amnesia
Symptoms	Inability to remember information about self, often related to a prior traumatic experience; amnesia can be localized or specific to an event or generalized for life-long events/identity	Dissociative amnesia: loss of memory related to important, often traumatic or stressful, events Dissociative fugue: all the features of dissociative amnesia accompanied by travel, during which the patient may appear normal to outside observers despite there being amnesia during the period of the fugue	Inability to recall important autobiographical memories, typically recent and related to trauma
Exclusions	Normal forgetting Other mental illness Neurocognitive disorder	Nonalcoholic organic amnesic syndrome Substance-induced amnesic disorder Postictal amnesia in epilepsy Postictal fugue in epilepsy	Other dissociative disorders, trance disorder Other mental disorder Substance or medication Other medical condition
Psychosocial consequences	Marked distress and/or impairment		Functional impairment
Symptom specifiers	***With dissociative fugue*** (traveling or wandering that is accompanied by amnesia)		With or without dissociative fugue

Table 47.
Depersonalization/Derealization Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Depersonalization/derealization disorder	Other dissociative (conversion) disorders	Depersonalization/derealization disorder
Symptoms	Depersonalization (sense of being detached from self or being an outside observer of one's own experiences, sense of unreality, and distorted time/perception) Derealization (sense of unreality or detachment from one's surroundings) During depersonalization or derealization, reality testing remains intact	Includes: Ganser syndrome (intentionally acting like one has a physical or mental illness despite not being sick) Multiple personalities	Persistent experience of either or both: ▸ Depersonalization: experiencing oneself as strange or unreal ▸ Derealization: experiencing other persons/places/objects as strange or unreal During depersonalization or derealization, reality testing remains intact
Required number of symptoms	One or both depersonalization and/or realization, in addition to intact reality testing during episodes		
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness		Other medical condition Substance or medication, including withdrawal Other mental illness
Psychosocial consequences	Marked distress and/or impairment		Marked distress and/or impairment

9. SOMATIC SYMPTOMS AND RELATED DISORDERS

Table 48.
Somatic Symptom Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Somatic symptom disorder	Somatization disorder	Bodily distress disorder
Duration	Symptoms persistent for a period of usually ≥6 months	≥2 years	Persistent, last ≥ several months
Symptoms	Persistent and recurrent thoughts related to the potential severity and seriousness of one's symptoms Out-of-proportion anxiety about these symptoms and overall health Spending excessive amounts of time and energy on these symptoms	Multiple recurring and frequently changing physical symptoms, often accompanied by a long history of involvement in the medical system, frequent use of health care services, and workups not revealing the clear cause of symptoms.	≥1 distressing bodily symptoms Excessive attention to symptoms (preoccupation with symptoms, repeated health care contacts) Attention persists despite reassurance from a healthcare provider
Required number of symptoms	≥1 of the above		
Exclusions		Malingering	Other mental illness
Psychosocial consequences	Marked distress and/or impairment	Disruption of social, interpersonal, and family behavior.	Functional impairment
Symptom specifiers	***With predominant pain***		
Course specifiers	**Persistent:** severe symptoms and impairment for ≥6 months		
Severity specifiers	**Mild:** only 1 of the above symptom criteria is met **Moderate:** ≥2 of the above symptom criteria are met **Severe:** ≥2 of the above symptom criteria are met, in addition to having multiple somatic symptoms or 1 extremely severe somatic symptom	Undifferentiated somatoform disorder (<2 years of less severe symptoms) Somatoform autonomic dysfunction (particularly involving autonomic arousal symptoms, in addition to other less specific complaints Persistent somatoform pain disorder (pain symptoms are predominant among somatic complaints)	Mild Moderate Severe

Table 49.
Illness Anxiety Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Illness anxiety disorder	Hypochondriacal disorder	Hypochondriasis
Duration	Symptoms persistent for a period ≥6 months		
Symptoms	Being excessively preoccupied with having or potentially acquiring a serious illness without somatic symptoms being present (or if present, only mild) Intense anxiety that is out of proportion to any potential risk (i.e., family history) that may exist for a given illness Performance of excessive health-related behaviors and/or presence of maladaptive behaviors or avoidance	Persistent preoccupation with potentially having ≥1 serious medical illness, with anxiety potentially manifesting as somatic complaints, anxiety regarding physical appearance, and potential depression/distress)	Persistent preoccupation or fear about the possibility of having ≥1 serious, progressive, or life-threatening illness, accompanied by Repetitive and excessive health-related behaviors (e.g., checking for illness) Avoidance behaviors related to health
Required number of symptoms	All of the above		
Exclusions	Other mental illness		Body dysmorphic disorder Bodily distress disorder Fear of cancer
Psychosocial consequences			Marked distress and/or impairment
Symptom specifiers	***Care-seeking type*** Care-avoidant type		
Comments		Note: body dysmorphic disorder is classified here.	

Table 50.
Conversion Disorder (Functional Neurologic Symptom Disorder/Dissociative Neurologic Symptom Disorder)

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Conversion disorder (functional neurologic symptom disorder)	Dissociative (conversion) disorders	Dissociative neurologic symptom disorder
Duration			≥1 hour
Symptoms	≥1 symptom of a change in voluntary motor or sensory function; Clinical exam does not identify a correlation between symptoms and a recognized medical/neurologic illness		Abnormal integration of motor/sensory/cognitive functions Symptoms are not consistent with a recognized neurologic disorder
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness		Other dissociative disorder Other mental disorder Substance or medication Other medical disorder
Psychosocial consequences	Marked distress and/or impairment in functioning		Functional impairment
Symptom specifiers	***With weakness or paralysis*** With abnormal movement With swallowing symptoms With speech symptom With attacks or seizures With anesthesia or sensory loss With special sensory symptoms (i.e., vision, olfaction, hearing) With mixed symptoms	**Dissociative stupor** **Dissociative motor disorder** (can include limb, speech, or gait symptoms) **Dissociative convulsions** (mimic epileptic seizures, without characteristic features of epileptiform seizures) **Dissociative anesthesia and sensory loss** **Mixed dissociative (conversion) disorders**	With visual disturbance With auditory disturbance With vertigo or dizziness With other sensory disturbance With nonepileptic seizures With speech disturbance With paresis or weakness With gait disturbance With movement disturbance With cognitive symptoms With other specified symptoms With other unspecified symptoms
Course specifiers	**Acute episode** (<6 months) **Persistent** (≥6 months) **With psychological stressor** **Without psychological stressor**		

Table 51.
Factitious Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Factitious disorder	Intentional production or feigning of symptoms or disabilities, either physical or psychological (factitious disorder)	Factitious disorder
Symptoms	**Factitious disorder imposed on self:** ▸ Act of falsifying symptoms and clinical findings in one's self ▸ Presenting one's self to others as ill ▸ Deceptive behaviors present outside of identifiable external reward or motivation **Factitious disorder imposed on another:** ▸ Act of falsifying symptoms/injury/disease and clinical findings in another individual ▸ Presenting an individual in whom symptoms have been falsified to others as being ill ▸ Deceptive behaviors present outside of identifiable external reward or motivation	Feigning symptoms for no clear reason or motivation, with the aim being to take on the sick role.	Intentional feigning/falsifying/inducing/aggravating medical/psychological/behavioral signs and symptoms, or injury in self or others, associated with an identified deception.
Exclusions	Other mental illness	Factitious dermatitis Person feigning illness with obvious motivation	Malingering
Symptom specifiers			Factitious disorder imposed on self Factitious disorder imposed on another
Course specifiers	**Single episode** Recurrent episodes (≥2 discrete events)		
Comments	***Note: In factitious disorder imposed on another, the perpetrator receives the diagnosis, not the victim.***		

10. FEEDING AND EATING DISORDERS

Table 52.
Pica

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Pica	Pica in infancy and childhood Pica in adults	Pica
Duration	≥1 month	Persistent	Persistent, but can be episodic or variable, or chronic and continuous
Symptoms	Eating substances that are not foods and not nutritional Behavior is inappropriate for development level	Eating non-nutritive substances	Consuming non-nutritive substances Severe enough to require clinical attention Inappropriate for age
Psychosocial consequences			Risks to health/functional impairment
Exclusions	Other medical condition Other mental illness		Other medical conditions, such as a nutritional deficiency
Course specifiers			It can be episodic or variable, or chronic and continuous
Severity specifiers	In remission		

Table 53.
Rumination Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Rumination disorder	Feeding disorder of infancy and childhood: rumination disorder of infancy	Rumination-regurgitation disorder
Duration	≥1 month		≥ Several times per week Sustained for several weeks
Symptoms	Repeated regurgitation of food		Intentional regurgitation of food
Psychosocial consequences			Risks to health/functional impairment
Exclusions	Other eating disorder Other mental illness Other medical conditions, including gastrointestinal disorders		Age <2 Other medical condition Adult rumination syndrome Nausea or vomiting
Severity specifiers	In remission		

Table 54.
Avoidant/Restrictive Food Intake Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Avoidant/restrictive food intake disorder	Other eating disorder	Avoidant/restrictive food intake disorder
Symptoms	Eating/feeding disturbance associated with: ▶ Significant weight loss/lack of expected weight gain ▶ Significant nutritional deficiency ▶ Needing enteral feeding or oral supplements		Avoidance or restriction of food intake ▶ Insufficient intake for nutritional needs ▶ Nutritional deficiencies ▶ Dependence on supplements or tube feeding ▶ Other negative effects on health
Required number of symptoms			Any of the above or functional impairment
Psychosocial consequences	Functional impairment		Functional impairment
Exclusions	Food insecurity Culturally sanctioned practice Other eating disorder Other medical condition		Food insecurity Other medical condition Substance or medication, including withdrawal Other mental illness
Course specifiers	In remission		

Table 55.
Anorexia Nervosa

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Anorexia nervosa	Anorexia nervosa	Anorexia nervosa
Symptoms	Food restriction leading to abnormally low weight Fear of gaining weight and behaviors to prevent weight gain Distorted body image ▶ Misperceiving weight of shape ▶ Self-evaluation based on thinness, lack of recognition of the seriousness of one’s weight	Deliberate weight loss induced by the patient Fear of being fat or flabby Associated physiologic disturbances due to low weight Specific behaviors: ▶ Restricted diet ▶ Excess exercise ▶ Binging behavior ▶ Use of appetite suppressants and diuretics	Low body weight Typically BMI <18.5 kg/m^2 in adults, and under 5th percentile in children and adolescents Pattern or restrictive eating or other behavior for maintaining a low weight Usually associated with fear of weight gain Excess preoccupation with body weight or shape
Required number of symptoms	All		
Exclusions		Loss of appetite (physical or psychological)	Other medical condition Food insecurity
Symptom specifiers	Restricting type: primary behaviors are dieting, fasting, and exercise for the last 3 months Binge eating type: binging and purging behavior for the last 3 months. It can include the use of laxatives or other substances to aid in purging.		
Course specifiers	Partial remission: symptoms present but no longer an abnormally low weight Full remission: no symptoms for a sustained period		
Severity specifiers	Severity is measured by BMI level Mild: BMI ≥17 kg/m^2 Moderate: BMI ≥16, <17 kg/m^2 Severe: BMI ≥15, <16 kg/m^2 Extreme: BMI <15 kg/m^2		
Comments		If lacking core symptoms, the diagnosis of “Atypical	

		anorexia nervosa” is made.	

Table 56.
Bulimia Nervosa

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Bulimia nervosa	Bulimia nervosa	Bulimia nervosa
Duration	Occurs ≥1/wk for 3 months		Usually ≥1/wk for 1 month
Symptoms	Repeated binge-eating episodes ▶ Occurring within 2 hours period ▶ Loss of control during the episode Compensatory behaviors to prevent weight gain, such as ▶ Purging ▶ Laxatives ▶ Diuretics, other substances ▶ Excessive exercise ▶ Fasting Self-evaluation based on weight and shape	Binging Preoccupation with weight control Preoccupation with body shape and weight Associated physiologic disturbances due to repeated vomiting Specific compensatory behaviors: ▶ Vomiting ▶ Use of purgatives	Frequent episodes of binge eating Compensatory behaviors to prevent weight gain, most commonly purging Excess preoccupation with body weight or shape
Required number of symptoms	All	Not specified	
Psychosocial consequences			Distress or functional impairment
Exclusions	Does not occur only during episodes of anorexia nervosa		Anorexia nervosa
Course specifiers	Partial remission: full symptoms no longer met for a sustained time Full remission: no symptoms for a sustained period		
Severity specifiers	Severity is measured by the average number of compensatory behaviors in a week’s time Mild: 1–3 Moderate: 4–7 Severe: 8–13 Extreme: 14+		

Table 57.
Binge Eating Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Binge eating disorder	Atypical bulimia nervosa	Binge eating disorder
Duration	≥1/wk for 3 months		Usually ≥1/wk for 1 month
Symptoms	Repeated binge-eating episodes ▶ Occurring within 2 hours period ▶ Loss of control during the episode Binge-associated behaviors or reactions ▶ Eating quicker than normal ▶ Eating until uncomfortably full ▶ Eating despite not being hungry ▶ Eating alone to avoid embarrassment ▶ Feeling guilty or disgusted after eating	Similar to ICD-10 bulimia nervosa minus the specific compensatory behaviors	Frequent episodes of binge eating No compensatory behaviors to lose weight
Required number of symptoms	Binge behaviors + ≥3 of the associated behaviors or reactions		
Psychosocial consequences	Marked distress		Distress or functional impairment
Exclusions	No compensatory behavior as in bulimia nervosa		Bulimia nervosa Other medical condition Substance or medication, including withdrawal Other mental illness
Course specifiers	Partial remission: occurrences are less frequent (<1 episode/wk) Full remission: no symptoms for a sustained period		
Severity specifiers	Severity is measured by the average number of compensatory behaviors in a week's time Mild: 1–3 Moderate: 4–7 Severe: 8–13 Extreme: 14+		

11. ELIMINATION DISORDERS

Table 58.
Enuresis

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Enuresis	Nonorganic enuresis	Enuresis
Duration	Occurring ≥2/wk for a minimum of 3 consecutive months		Several times per week for several months
Symptoms	Urinating into bed or clothes either voluntary or unintentionally	Involuntary voiding of urine Abnormal for age	Repeated and persistent voiding of urine into bed or clothes Inappropriate for developmental age
Required number of symptoms			
Exclusions	Age <5 Substance use Other medical condition	Other medical condition	Other medical condition Substance or medication
Symptom specifiers	***Nocturnal only*** ***Diurnal only*** ***Nocturnal and diurnal***		

Table 59.
Encopresis

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Encopresis	Nonorganic encopresis	Encopresis
Duration	≥1/month for ≥3 consecutive months		≥1/month for several months
Symptoms	Passing stool into clothes or onto the floor	A pattern of voluntarily or involuntarily passing feces in places that are inappropriate within the sociocultural context.	Repeated and persistent passage of feces in inappropriate places Inappropriate for developmental age (4)
Exclusions	Age <4 Substance use Another medical condition other than once causing constipation	Organic causes of encopresis	Other medical condition Substance or medication, including withdrawal
Severity specifiers	With constipation and overflow incontinence Without constipation and overflow incontinence		With constipation and overflow incontinence Without constipation and overflow incontinence

12. SLEEP DISORDERS

Table 60.
Insomnia Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Insomnia disorder	Disorders of initiating and maintaining sleep (insomnias)	Insomnia disorders
Duration	≥3 nights/wk for ≥3 months		
Symptoms	Dissatisfaction with the quality of sleep due to: ▶ Difficulty falling asleep ▶ Difficulty maintaining sleep due to frequent awakening ▶ Experiencing early morning awakening	Disorders characterized by difficulties with falling asleep and/or staying asleep	Difficulty with initiating, maintaining, or consolidating sleep, or poor quality of sleep despite adequate opportunities to sleep
Required number of symptoms	Any of the above		
Exclusions	Medical disorder Substance or medication Other sleep–wake disorders	Nightmares Nonorganic sleep disorders Sleep terrors Sleepwalking	
Psychosocial consequences	Distress or functional impairment		Daytime impairment
Symptom specifiers	**With nonsleep disorder mental comorbidity** (including substance use disorder) **With other medical comorbidity** **With other sleep disorder**		
Severity specifiers			
Course specifiers	**Episodic** (1–3 months) **Persistent** (>3 months) **Recurrent** (≥2 episodes/year)		

Table 61.
Hypersomnolence Disorder/Idiopathic Hypersomnia

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Hypersomnolence disorder		Idiopathic hypersomnia
Duration	≥3 nights/wk for ≥3 months		Daily period for several months
Symptoms	Excessive sleepiness with Recurrent periods of sleep within the same day Nonrestorative sleep lasting more than 9 hours Difficulty becoming fully awake		Need to sleep Daytime lapses into sleep Mean sleep latency of ≤8 minutes or 24-hour sleep time ≥11 hours (determined on polysomnography) Prolonged and severe sleep inertia
Required number of symptoms	One of the above		
Exclusions	Other sleep disorder Substance or medication Other mental disorder Other medical disorder		Cataplexy Hypocretin deficiency Narcolepsy
Psychosocial consequences	Distress or functional impairment		
Symptom specifiers	With mental disorder With medical condition With another sleep disorder		
Severity specifiers	Mild Moderate Severe		
Course specifiers	Acute Subacute Persistent		

Table 62.
Narcolepsy

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Narcolepsy	Narcolepsy and cataplexy	Narcolepsy
Duration	Symptoms present ≥3 times per week for ≥3 months		
Symptoms	Excessive daytime sleepiness with Cataplexy defined as ▶ Brief losses in muscle tone precipitated by laughing or joking ▶ Abnormal jaw-opening or global hypotonia without a clear emotional trigger CSF hypocretin deficiency REM sleep latency <15 minutes on polysomnography OR mean sleep latency <8 minutes on multiple sleep latency testing with >sleep-onset REM-sleep periods	Episodes of daytime sleepiness occurring despite adequate sleep, often associated with cataplexy, and uncontrollable lapses in consciousness	Need to sleep Daytime lapses into sleep Mean sleep latency of <8 minutes ≥2 sleep-onset REM periods on multiple sleep latency testing or ≥1 sleep-onset REM periods on multiple sleep latency testing and 1 on preceding polysomnography. Sleep is disturbed, and brief naps are typically refreshing
Required number of symptoms	Presence of excessive daytime sleepiness in addition to ≥1 of the above		
Exclusions	Substance use disorder Another sleep–wake disorder	Nightmares Nonorganic sleep disorders Sleep terrors Sleepwalking	
Symptom specifiers	Narcolepsy with cataplexy or hypocretin deficiency Narcolepsy without cataplexy and without hypocretin deficiency or deficiency is unmeasured Narcolepsy with cataplexy or hypocretin deficiency due to a medical condition Narcolepsy with cataplexy and without hypocretin deficiency due to a medical condition		Type 1 with cataplexy and hypocretin deficiency Type 2 without cataplexy without hypocretin deficiency
Severity specifiers	**Mild:** infrequent cataplexy (less than 1/wk), with		

naps only 1–2 times daily, and only mildly or intermittently disturbed nighttime sleep

Moderate: cataplexy 1/day or every few days, in addition to disturbed nighttime sleep and need for multiple naps daily

Severe: drug-resistant with near-constant somnolence and multiple attacks per day, in addition to disturbed night-time sleep

Table 63.
Circadian Rhythm Sleep Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Circadian rhythm sleep disorder	Disorders of sleep–wake schedule **Delayed sleep phase syndrome** **Irregular sleep–wake pattern**	Circadian rhythm sleep-wake disorders
Duration	**Episodic** (lasting 1–3 months) **Persistent** (lasting >3 months) **Recurrent** (>2 episodes within 1 year)		
Symptoms	Disturbed sleep due to alteration in the circadian system Sleep disruption leading to excessive daytime sleepiness Sleep disturbance leads to impairment and/or distress	Persistent sleep disturbance (i.e., insomnia or excessive daytime sleepiness) due to discrepant circadian rhythm and environmental demands Disruption of the normal 24-hour circadian cycle	Disturbances of the sleep-wake cycle due to alterations of the circadian time-keeping system.
Required number of symptoms	All of the above	One of the above	
Exclusions	Other medical condition Substance or medication, including withdrawal	Nightmares Nonorganic sleep disorders Sleep terrors Sleepwalking	
Psychosocial consequences	Marked distress and/or impairment		
Symptom specifiers	Delayed sleep phase type Familial Overlapping with non–24-hour sleep–wake type Advanced sleep phase type Familial Irregular sleep–wake type Non–24-hour sleep-wake type Shift work type Unspecified type		Delayed sleep-wake phase disorder Advanced sleep-wake phase disorder Irregular sleep-wake rhythm disorder Non–24-hour sleep-wake rhythm disorder Circadian rhythm sleep-wake disorder, shift work type Circadian rhythm sleep-wake disorder, jet lag type Circadian rhythm sleep-wake disorders, unspecified
Course specifiers	**Episodic** (lasting 1–3		

months)
Persistent (lasting >3 months)
Recurrent (≥2 within 1 year)

Table 64.
REM Sleep Behavior Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	REM sleep behavior disorder	REM sleep behavior disorder	REM sleep behavior disorder
Symptoms	Repeated episodes of arousal during sleep with vocalization or complex motor behavior Behaviors occur during REM sleep No confusion or disorientation present on awakening Either of the following also present: ▸ REM sleep without atonia on polysomnography ▸ History consistent with REM sleep behaviors with an established diagnosis of synucleinopathy (i.e., Parkinson disease) Symptoms not adequately explained by coexisting mental and medical disorders	Recurrent episodes of sudden and often violent motor activity during REM sleep, at times, related to self-injury or harming others, in addition to difficulty awakening the individual during episodes; episodes often associated with dream enactment	Repeat episodes of either Sleep related vocalization Complex movements Document on polysomnography or presumed to occur during REM sleep
Required number of symptoms	All of the above		
Exclusions	Other medical condition Substance or medication, including withdrawal Other mental illness	-	
Psychosocial consequences	Marked distress and/or impairment in functioning		
Severity specifiers			Mild Moderate Severe

Table 65.
Non–REM-Sleep Behavior Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Non–REM-sleep behavior disorder	Nonorganic disorders of the sleep–wake schedule: **Sleepwalking (somnambulism)** **Sleep terrors (night terrors)** **Nightmares**	Disorders of arousal from non-REM sleep
Symptoms	Recurrent episodes of incomplete awakening from sleep, accompanied by either ▸ Sleepwalking ▸ Sleep terrors Little dream recall, if any Amnesia for episodes Symptoms no adequately explained by other mental or medical disorders	Sleepwalking: altered state of consciousness in which sleep and wakefulness are combined; episodes associated with low levels of awareness, with no recall of event on awakening Sleep terrors: nighttime episodes of terror and panic associated with motor movement and vocalization, in addition to high levels of autonomic tone, associated with little to no recall of the event Nightmares: dreams associated with fear and negative emotion, with the presence of intact recall of dream content on awakening. Not associated with vocalization and body movement	Experiences or behaviors related to non-REM sleep.
Symptom specifiers	**Sleep terror type** Sleepwalking type ▸ **With sleep-related eating** ▸ **With sleep-related sexual behavior (sexsomnia)**		Confusional arousals Sleepwalking disorder Sleep terrors Sleep-related eating disorder

Table 66.
Breathing-Related Sleep Disorders

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Breathing-related sleep disorders: ▶ **Obstructive Sleep apnea hypopnea** ▶ **Central sleep apnea** ▶ **Sleep-related hypoventilation**	Sleep apnea **Central** **Obstructive**	Sleep-related breathing disorders
Symptoms	**Obstructive sleep apnea hypopnea:** ▶ Evidence on polysomnography of ≥5 obstructive apneas or hypopneas per hour of sleep with either: ▶ Nocturnal breathing disturbance (i.e., snoring, breathing pauses) ▶ Daytime sleepiness, fatigue ▶ Evidence on polysomnography of 15 more obstructive apneas and/or hypopneas per hour of sleep, regardless of accompanying symptoms **Central sleep apnea:** ▶ ≥5 central apneas per hour of sleep on polysomnography **Sleep-related hypoventilation:** ▶ Decreased respiration causing increased CO_2 levels, as correlated by polysomnography		Abnormalities of respiration during sleep
Required number of symptoms	**Obstructive sleep apnea hypopnea**: one of the above criteria must be met **Central sleep apnea:** all criteria met **Sleep-related hypoventilation:** all criteria met		
Exclusions	Another sleep disorder Use of a substance or medication	Pickwickian syndrome Sleep apnea of newborn	Apnea of newborn

Symptom specifiers	Obstructive sleep apnea hypopnea Central sleep apnea: Idiopathic central sleep apnea Cheyne–Stokes breathing Central sleep apnea comorbid with opioid use Sleep-related hypoventilation Idiopathic hypoventilation Congenital central alveolar hypoventilation Comorbid sleep-related hypoventilation		Central sleep apnea Obstructive sleep apnea ≥15 obstructive events/hour or ≥5 events plus symptoms or distress or disorder results Sleep-related hypoventilation or hypoxemia Sleep-related Cheynes-Stokes respiration
Severity specifiers	Obstructive sleep apnea hypopnea **Mild:** apnea hypopnea index is <15 **Moderate**: apnea hypopnea index 15–30 **Severe**: apnea hypopnea index >30 **Central sleep apnea:** severity based on the frequency of breathing disturbance as well as the severity of oxygen desaturation/sleep fragmentation. **Sleep-related hypoventilation:** severity is based on the degree of hypoxemia/hypercarbia, in addition to the presence of end-organ impairment. Blood gas abnormality during wakefulness is an indicator of more severe illness.		

Table 67.
Nightmare Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Nightmare disorder	Nonorganic disorders of the sleep–wake schedule **Sleep terrors** **Nightmares**	Nightmare disorder
Symptoms	A pattern of experiencing long, dysphoric, and vividly remembered dreams that are often threatening in nature Rapid orientation and alertness on awakening Not adequately explained by a coexisting mental or medical disorder	Sleep terrors: nighttime episodes of terror and panic associated with motor movement and vocalization, in addition to high levels of autonomic tone, associated with little to no recall of the event Nightmares: dreams associated with fear and negative emotion, with the presence of intact recall of dream content on awakening. Not associated with vocalization and body movement	Recurrent, vivid, and dysphoric dreams
Required number of symptoms	All of the above		
Exclusions	Result of ▶ Effects of a substance or medication		
Psychosocial consequences	Marked distress and/or impairment in areas of functioning	Marked distress and/or impairment in areas of functioning	
Symptom specifiers	**During sleep onset** With associated nonsleep disorder (including substance use disorder) With associated other medical condition With associated other sleep disorder		
Severity specifiers	**Mild** (<1 episode/wk) **Moderate** (≥1 episodes per week, but less than nightly) **Severe** (nightly episodes)		
Course specifiers	**Acute** (duration <1 month) **Subacute** (1–6 months) **Persistent** (>6 months)		

Table 68.
Restless Legs Syndrome

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Restless legs syndrome	Other specified extrapyramidal and movement disorders Restless legs syndrome	Restless legs syndrome
Duration	Symptoms occur ≥3 times per week for ≥3 months		
Symptoms	Urge to move legs, including worsening urge at night, with urge relieved by movement	Experiencing a strong urge to move legs in order to relieve discomfort; often occurs while lying down or sitting and tends to be worse at night	Strong urge to move limbs
Required number of symptoms	All of the above		
Exclusions	Akathisia Effects of a substance or medication Another mental disorder or medical condition Behavioral condition (i.e., habitual movements)		
Psychosocial consequences	Marked distress and/or impairment	Marked distress and/or impairment	Marked distress and/or impairment

13. SEXUAL DISORDERS

Table 69.
Delayed Ejaculation

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Delayed ejaculation	Orgasmic dysfunction	Male delayed ejaculation
Duration	≥6 months duration of symptoms		
Symptoms	Delay in ejaculation Absence or reduced frequency of ejaculation	Marked delay or absence of orgasm	Inability to achieve or increased latency of ejaculation despite adequate stimulation
Required number of symptoms	Either or both of the above symptoms		
Exclusions	Nonsexual mental disorder Significant relationship distress Side effects of a medication Substance use Another medical condition	Organic causes of sexual dysfunction	
Psychosocial consequences	Marked distress		
Symptom specifiers	***Generalized vs. Situational***		Associated with a medical condition, injury, or the effects of surgery or radiation treatment Associated with psychological or behavioral factors, including mental disorders Associated with the use of psychoactive substances or medication Associated with a lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders
Course specifiers	***Lifelong vs. Acquired***		
Severity specifiers	**Mild:** symptoms causing mild distress **Moderate:** symptoms causing moderate		

	distress **Severe:** symptoms causing severe distress	
Comments		Note: ICD-10 classifies orgasmic dysfunction as occurring in men and women, including delayed ejaculation in this category as per Table 16-5

Table 70.
Erectile Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Erectile disorder	Failure of genital response	Male erectile dysfunction
Duration	≥6 months duration of symptoms		
Symptoms	Difficulty achieving an erection Difficulty maintaining erection Reduction in erectile rigidity	Male: difficulty developing maintaining or developing an erection for satisfactory sexual intercourse Female: can present with vaginal dryness or lack of adequate lubrication for sexual intercourse	Decreased or no ability to attain/sustain penile erection despite adequate sexual desire and stimulation
Required number of symptoms	≥1 of the above present in all or most sexual encounters		
Exclusions	Nonsexual mental disorder Significant relationship distress Side effects of a medication Substance use Another medical condition		
Psychosocial consequences	Marked distress		
Symptom specifiers	***Generalized vs. Situational***		Associated with a medical condition, injury, or the effects of surgery or radiation treatment Associated with psychological or behavioral factors, including mental disorders Associated with the use of psychoactive substances or medication Associated with a lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders

Course specifiers	***Lifelong vs. Acquired***	
Severity specifiers	**Mild:** symptoms causing mild distress **Moderate:** symptoms causing moderate distress **Severe:** symptoms causing severe distress	
Comments		Note: ICD-10 classifies this diagnosis as including male erectile disorder as well as female sexual arousal disorder

Table 71.
Female Orgasmic Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Female orgasmic disorder	Orgasmic dysfunction	Anorgasmia
Duration	≥6 months duration of symptoms		
Symptoms	Delay or reduced frequency of orgasm Reduced intensity of orgasm	Marked delay or absence of orgasm	Absence or infrequency of orgasm or diminished intensity. In women can include significant delay in orgasm.
Required number of symptoms	Either of the above is present for most or all sexual encounters		
Exclusions	Nonsexual mental disorder Significant relationship distress Side effects of a medication Substance use Another medical condition		
Psychosocial consequences	Marked distress		
Symptom specifiers	***Generalized vs. Situational***		Associated with a medical condition, injury, or the effects of surgery or radiation treatment Associated with psychological or behavioral factors, including mental disorders Associated with the use of psychoactive substances or medication Associated with a lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders Associated with the use of psychoactive substances or medication

			Associated with a lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders
Course specifiers	***Lifelong vs. Acquired*** Never experienced an orgasm under any conditions		
Severity specifiers	**Mild:** symptoms causing mild distress **Moderate:** symptoms causing moderate distress **Severe:** symptoms causing severe distress		
Comments		Note: ICD-10 classifies orgasmic dysfunction as occurring in men and women, including delayed ejaculation in this category as per Table 16-6	

Table 72.
Female Sexual Interest/Arousal Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Female sexual interest/arousal disorder	Lack or loss of sexual desire Sexual aversion and lack of sexual enjoyment	Female sexual arousal dysfunction
Duration	≥6 months duration of symptoms		
Symptoms	Symptoms of reduced sexual interest or arousal, such as in: ▶ Reduced interest in sex ▶ Reduced sexual thoughts or fantasies ▶ Reduced initiation of/receptiveness to sexual activity ▶ Absent or reduced pleasure from sexual activity ▶ Absent or reduced pleasure from internal or external sexual cues ▶ Absent or reduced genital sensations during sexual activity	Lack or loss of sexual desire not attributable to physiologic difficulties related to intercourse Sexual aversion due to anxiety and subsequent avoidance of sexual activity, or lack of enjoyment given that orgasm is not accompanied by appropriate pleasure.	Absence or reduction in response to sexual stimulation despite adequate stimulation. Areas that may be affected include: ▶ Genital response ▶ Nongenital response (e.g., nipples, skin, physiologic) ▶ Sexual arousal when stimulated
Required number of symptoms	≥3 of the above symptoms present during most or all sexual encounters		
Exclusions	Nonsexual mental disorder Significant relationship distress Side effects of a medication Substance use Another medical condition		
Psychosocial consequences	Marked distress		
Symptom specifiers	***Generalized vs. Situational***		Associated with medical condition, injury, or the effects of surgery or radiation treatment Associated with psychological or behavioral factors, including mental disorders Associated with the use of psychoactive substances or medication

			Associated with a lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders
			Associated with the use of psychoactive substances or medication Associated with lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders
Course specifiers	***Lifelong vs. Acquired***		
Severity specifiers	**Mild:** symptoms causing mild distress **Moderate:** symptoms causing moderate distress **Severe:** symptoms causing severe distress		

Table 73.
Genito-Pelvic Pain/Penetration Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	**Genito-pelvic pain/penetration disorder**	**Nonorganic vaginismus** Nonorganic dyspareunia	**Sexual pain-penetration disorder**
Duration	≥6 months duration of symptoms		
Symptoms	Difficulties with vaginal penetration Pain during intercourse/with penetration Fear or anxiety about pain during sexual encounters Tension or tightening of pelvic muscles during attempted penetration	***Vaginismus***: spasm of pelvic floor muscles around the vagina, causing pain and difficulties with penetration Dyspareunia: pain or discomfort related to penile penetration or intercourse	
Required number of symptoms	≥1 of the above		
Exclusions	Nonsexual mental disorder Significant relationship distress Side effects of a medication Substance use Another medical condition	Result of: Organic causes of vaginismus or dyspareunia	
Psychosocial consequences	Marked distress		
Symptom specifiers			Associated with a medical condition, injury, or the effects of surgery or radiation treatment Associated with psychological or behavioral factors, including mental disorders Associated with the use of psychoactive substances or medication Associated with lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in

			sexual dysfunctions and sexual pain disorders Associated with the use of psychoactive substances or medication Associated with lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders
Course specifiers	***Lifelong vs. Acquired***		
Severity specifiers	**Mild:** symptoms causing mild distress **Moderate:** symptoms causing moderate distress **Severe:** symptoms causing severe distress		
Comments		Note: ICD-10 classifies orgasmic dysfunction as occurring in men and women, including delayed ejaculation in this category as per Table 16-5	

Table 74.
Male Hypoactive Sexual Desire Disorder

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Male hypoactive sexual desire disorder	Lack or loss of sexual desire	Hypoactive sexual desire dysfunction
Duration	Persistent or recurrent for about 6 months		
Symptoms	Decreased sexual/erotic thoughts, fantasies, and sexual desire	Loss of sexual desire	Absent or decreased desire or motivation for sex: ► Reduced/absent desire ► Reduced/absent response to cues ► Inability to sustain desire or motivation once begun
Required number of symptoms			Any of the bulleted points
Exclusions	Other mental disorder Relationship distress Significant stressors Substance or medication Other medical condition	Other sexual difficulty	
Psychosocial consequences	Distress		
Symptom specifiers			Associated with a medical condition, injury, or the effects of surgery or radiation treatment Associated with psychological or behavioral factors, including mental disorders Associated with the use of psychoactive substances or medication Associated with a lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders Associated with the use of psychoactive

			substances or medication Associated with a lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders
Course specifiers	Lifelong vs. Acquired Generalized vs. Situational ***Never experienced an orgasm under any conditions***		
Severity specifiers	**Mild:** symptoms causing mild distress **Moderate:** symptoms causing moderate distress **Severe:** symptoms causing severe distress		
Comments	Requires clinical judgment to decide if not age or situationally appropriate		

Table 75.
Premature (Early) Ejaculation

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Premature (early) ejaculation	Premature ejaculation	Male early ejaculation
Duration	≥6 months duration of symptoms		Persistent or episodic for several months
Symptoms	A pattern of ejaculation within 1 minute of penetration and before the affected individual wishes for it to occur	Difficulty controlling ejaculation such that both partners cannot sufficiently enjoy sexual intercourse	Ejaculation before or shortly after penetration or stimulation.
Required number of symptoms	Above symptom present in all or most sexual encounters		
Exclusions			
Psychosocial consequences	Marked distress		
Symptom specifiers	***Generalized vs. Situational***		Associated with a medical condition, injury, or the effects of surgery or radiation treatment Associated with psychological or behavioral factors, including mental disorders Associated with the use of psychoactive substances or medication Associated with a lack of knowledge or experience Associated with relationship factors Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders Associated with the use of psychoactive substances or medication Associated with a lack of knowledge or experience Associated with relationship factors

			Associated with cultural factors Other specific etiologic considerations in sexual dysfunctions and sexual pain disorders
Course specifiers	***Lifelong vs. Acquired***		
Severity specifiers	**Mild:** ejaculation within 30 seconds to 1 minute of penetration **Moderate:** ejaculation within 15–30 seconds of penetration **Severe:** ejaculation within 15 seconds of penetration		

14. GENDER DYSPHORIA

Table 76.
Gender Dysphoria in Children/Gender Incongruence of Childhood

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Gender dysphoria in children	Gender identity disorder of childhood	Gender incongruence of childhood
Duration	≥6 months		2 years
Symptoms	Desire to be other gender or insistence one is that gender Preference for cross-dressing in boys, preference for typical masculine, and resistance to typical feminine clothing in girls. Preference for cross-gender roles during play Preference for toys/games/activities stereotypically used by another gender Preference for playmates of another gender Rejection of toys/games/activities stereotypically of one's assigned gender Dislike of one's sexual anatomy A desire for sex characteristics of one's experienced gender	Distress about assigned sex	Incongruence between experienced/expressed gender and assigned sex Strong desire to be a different gender Dislike of their sexual anatomy/anticipated secondary sex characteristic A desire for secondary sex characteristics to be of a different gender Activities and play typical of the experienced gender
Required number of symptoms	6		
Psychosocial consequences	Distress or psychosocial impairment		
Exclusions		Gender variant behavior or preferences	Gender variant behavior or preferences
Symptom specifiers	With a disorder/difference of sex development (e.g., congenital disorder)		

Table 77.
Gender Dysphoria in Adolescents and Adults/Gender Incongruence of Adolescence or Adulthood

Disorder	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Gender dysphoria in adolescents and adults	Transsexualism	Gender incongruence of adolescence or adulthood
Duration	≥6 months		
Symptoms	Incongruence between experienced/expressed gender and primary or secondary sex characteristics Desire to be rid of primary/secondary sex characteristics or prevent their development The desire for primary/secondary sex characteristics of another gender Desire to be a different gender Desire to be treated as a different gender A conviction that they feel and react like a different gender	Desire to live and be accepted as a member of the opposite sex Discomfort with one's anatomic sex or sense that it is inappropriate Desire to transition	Incongruence between experienced/expressed gender and assigned sex Desire to transition
Required number of	2		
Psychosocial consequences	Distress or psychosocial impairment		
Exclusions			Gender variant behavior or preferences
Symptom specifiers	With a disorder/difference of sex development (e.g., congenital disorder)		
Course specifiers	Post-transition: living as experienced gender and has undergone ≥ one gender-affirming medical procedure		

15. DISRUPTIVE, IMPULSE-CONTROL, AND CONDUCT DISORDERS

Table 78.
Oppositional Defiant Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Oppositional defiant disorder	Oppositional defiant disorder	Oppositional defiant disorder
Duration	≥6 months If <5 years, occurs most days If ≥5 years, occurs ≥1 time/wk		Extended period
Symptoms	Loses temper Sensitive/easily annoyed Angry/resentful Argues with authorities Disobeys authorities or rules Annoys others on purpose Blames others Spiteful or vindictive ≥2×/past 6 months	Conduct disorder, usually in younger children, with: ▶ Disobedience ▶ Defiance ▶ Disruptive behavior No delinquency or severe aggression or dissocial behaviors	Noncompliant, defiant, and disobedient behaviors inappropriate for age with: ▶ Difficulty getting along with others ▶ Provocative, spiteful or vindictive ▶ Extremely irritable or angry
Required number of symptoms	≥4		
Psychosocial consequences	Distress or psychosocial impairment		Distress or psychosocial impairment
Exclusions	Substance- or medication-induced, including withdrawal Other mental disorder		Relationship problems (i.e., response to overly harsh parents or teachers)
Symptom specifiers			With or without chronic irritability-anger With limited prosocial emotions With typical prosocial emotions
Severity specifiers	**Mild:** occurs in 1 setting **Moderate:** occurs in ≥2 settings **Severe:** occurs in ≥3 settings		

Table 79.
Intermittent Explosive Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Intermittent explosive disorder	Other habit and impulse disorders	Intermittent explosive disorder
Duration	See below		≤3 months or 1 year if outburst are severe
Symptoms	Age ≥6Recurrent spontaneous outbursts that are an overreaction to an event, with: ▸ Verbal/physical aggression 2×/wk for ≥3 months ▸ 3 episodes resulting in harm/destruction over 1 year period	Pattern of repeated maladaptive behaviors, not better explained by another disorder, associated with prodromal tension and release at time of act.	Age ≥6 Brief impulsive/reactive episodes of verbal/physical aggression. Out of proportion to the circumstance and developmental age
Required number of symptoms	All of the above		
Psychosocial consequences	Distress or psychosocial impairment		Distress or psychosocial impairment
Exclusions	Other medical condition Substance- or medication-induced, including withdrawal Other mental disorder		Other medical condition Substance- or medication-induced, including withdrawal Other mental disorder
Course specifiers	***Persistent:*** >12 months		
Severity specifiers	***Severe:*** if all symptom criteria met at relatively high level		

Table 80.
Conduct Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Conduct disorder	Conduct disorder	Conduct-dissocial disorder
Duration	≥1 symptom for ≥6 months Other symptoms ≥1 year	6 months or longer	≥12 months, persistent and recurrent behavior
Symptoms	Bullying others Initiating physical fights Use of a weapon causing serious harm Physical cruelty toward others Physical cruelty toward animals Stealing while physically confronting a victim Forcing sexual activity on another Deliberately setting a fire Deliberately destroying someone’s property Breaking into another’s property Lying to obtain goods or favors or to avoid obligations Stealing items of high value without necessarily confronting victim Staying out at night against parental restrictions ≤age 13 ≥2 episodes of running away (or 1× if prolonged) Frequent truancy ≤age 13	Repeated and pervasive pattern of antisocial behavior, aggression and defiance that are significantly deviant for age-appropriate expectations. Actions may involve cruelty, bullying, destructiveness, lying, running away/truancy, and anger.	Violating rights or others/laws/norms, including ▶ Aggression toward people/animals ▶ Destruction of property ▶ Deceit/theft ▶ Serious rule violations
Required number of symptoms	3		
Psychosocial consequences			Distress or psychosocial impairment
Symptom specifiers	**With limited prosocial emotions:** demonstrating at least two of the following over 12 months an in multiple contexts: ▶ ***Lack of remorse or guilt*** ▶ ***Callous—lack of empathy*** ▶ ***Unconcerned about performance***	**Conduct disorder confined to the family** context (within nuclear family) U**nsocialized conduct disorder** (predominant aggression, often toward other children) **Socialized conduct disorder** (despite aggression, there is	With limited prosocial emotions With typical prosocial emotions

	▶ ***Shallow or deficient affect***	good integration into their peer group)	
Course specifiers	**Childhood onset type** (symptoms present prior to age 10) **Adolescent onset type** (no symptoms prior to age 10)		Childhood onset Adolescent onset
Severity specifiers	**Mild:** few symptoms in excess of number needed to make diagnosis, with relatively minor resultant harm to others **Moderate:** intermediate symptoms and consequences **Severe:** many issues in excess of minimum needed for diagnosis, with resultant harm to others being considerable		

Table 81.
Pyromania

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Pyromania	Pyromania	Pyromania
Symptoms	Fire setting 1+ incidents Deliberate and purposeful Fascination/preoccupation with fire and related subjects Followed by a period of gratification or release	Fire setting Multiple acts or attempts No apparent motive Preoccupied by fire, burning, and related phenomena Preceded by a period of tension Followed by a period of excitement	Fire setting Strong impulse resulting in multiple acts or attempts No external motivation or gain Fascination/preoccupation with fire and related subjects Increased tension/affect before episodes Followed by a period of gratification or release
Required number of symptoms	All of the above	All of the above	
Exclusions	▶ Consult disorder ▶ Mania ▶ Antisocial personality disorder ▶ Psychosis ▶ Impaired cognition or judgment Motivated by: ▶ Desire for a perceived financial or social benefit ▶ Sociopolitical ideology ▶ Need to conceal criminal activity ▶ Anger ▶ Vengeance	▶ Dissocial personality disorder ▶ Alcohol of substance disorder ▶ Feigned illness ▶ Conduct disorder ▶ Organic mental disorder ▶ Schizophrenia	Disorder of intellectual development Substance- or medication-induced, including withdrawal Other mental disorder
Comments		Included among the habit and impulse disorders	

Table 82.
Kleptomania

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Kleptomania	Pathologic stealing (kleptomania)	Kleptomania
Symptoms	Recurrent stealing Failure to resist the impulse to steal Items stolen are not needed Preceded by a period of tension Followed by a period of gratification or release	Failure to resist impulse to steal Items stolen are not needed Usually preceded by period of tension Usually followed by a period of gratification or release	Failure to resist impulse to steal Items stolen are not needed Preceded by period of tension Followed by a period of gratification or release
Required number of symptoms	All of above		
Exclusions	Result of ▶ Anger ▶ Vengeance ▶ Psychosis Consult disorder Mania Antisocial personality disorder	Other mental disorder	Disorder of intellectual development Substance- or medication-induced, including withdrawal Other mental disorder
Comments		Included among the habit and impulse disorders	

16. SUBSTANCE USE AND ADDICTIVE DISORDERS

Table 83.
Substance Use Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Substance use disorder (indicate specific substance) ▶ Alcohol ▶ Cannabis ▶ Hallucinogens ▶ Inhalants ▶ Opioids ▶ Sedatives, Hypnotics, Anxiolytics ▶ Stimulants	Mental and behavioral disorders due to (indicate specific substance) Indicate if a dependence syndrome	Substance dependence (indicate specific substance)
Duration	Symptoms occur within 12 months		≥3 months
Symptoms	Impaired control ▶ Use of larger amounts/longer use than intended ▶ Persistent desire or unsuccessful efforts to reduce the use ▶ Significant time invested in obtaining, using, or recovering from a substance ▶ Cravings to use Social impairment ▶ Use interfering in the fulfillment of responsibilities ▶ Use despite social, personal, financial, health, and other consequences of substance use ▶ Reduction in other personal and interpersonal activities due to use Risky use ▶ Use in high-risk or dangerous situations ▶ Use despite recognition of potential physical or mental problems caused by substance use Pharmacologic criteria ▶ Tolerance ▶ Withdrawal (does not apply to inhalants or hallucinogens)	Behavioral, cognitive, and physiologic manifestations of repeated substance use Frequently associated with cravings to use the drug and difficulties controlling use Pattern of persistent use despite recognition of adverse consequences of use Prioritization of substance use over other social, financial, and personal obligations Frequently accompanied by tolerance and withdrawal states	Recurrent (episodic or continuous) use of a substance with associated impairment. ▶ Impaired control over the use ▶ Preference of substance to other obligations and activities ▶ Physiologic features, including tolerance or withdrawal

Required number of symptoms	≥2		≥2
Psychosocial consequences	Marked impairment and/or distress		
Exclusions		***Psychotic state*** Nonalcoholic Korsakov psychosis or syndrome	An episode of harmful use A harmful pattern of use
Symptom specifiers	**In a controlled environment:** currently in an environment where access to substances is restricted **Substance-specific specifiers:** Tobacco use disorder: On maintenance therapy Opioid use disorder: On maintenance therapy Hallucinogen use disorder: Specify the hallucinogen Inhalant use disorder: Specify the inhalant	***Associated specifiers:*** Psychotic disorder: psychotic symptoms following a psychoactive substance, not due to acute intoxication alone or due to withdrawal alone Amnesic syndrome: chronic impairment in memory due to the use	
Course specifiers	**In early remission:** no symptoms for 3–12 months (except cravings) In sustained remission: no symptoms >1 year (except cravings)		Current use Early full remission: 1–12 months Sustained partial remission: mostly abstinent for ≥12 months Sustained remission: fully abstinent for ≥12 months
Severity specifiers	**Mild**: 2–3 symptoms **Moderate**: 4–5 symptoms **Severe**: ≥6 symptoms		
Comments		Note: ICD additionally defines “Harmful use” as a pattern of use causing harm to health, both physical and/or mental. This classification is independent of the presence of a dependence syndrome.	Alternative diagnoses include: Harmful use of a substance: ≥1 month in which use of a substance causes physical or mental harm. A harmful pattern of use of a substance: regular or sporadic use of a substance that causes

physical or mental harm.

Table 84.
Substance Intoxication

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Substance intoxication ▶ Alcohol ▶ Caffeine ▶ Cannabis ▶ PCP, hallucinogens ▶ Inhalants ▶ Opioids ▶ Sedatives, hypnotics, anxiolytics ▶ Stimulants	Mental and behavioral disorders due to ▶ Use of alcohol ▶ Use of opioids ▶ Use of cannabinoids ▶ Use of sedatives or hypnotics ▶ Use of cocaine ▶ Use of other stimulants, including caffeine ▶ Use of hallucinogens ▶ Use of tobacco ▶ Use of volatile solvents Indicate if acute intoxication	Substance intoxication Disturbance in affect, behavior, perception, cognition, or consciousness after substance use Symptoms are known effects of the particular substance Symptoms are transient and improve as the substance is eliminated
Symptoms	Recent use of a substance Problematic behavior, mood, or cognition resulting ≥1 substance-specific symptoms of intoxication	Change in level of awareness, cognition, perception, behavior, and/or psychology following ingestion of a psychoactive substance Symptoms directly related to substance and resolve with time	
Required number of symptoms	The required minimum number of symptoms varies by substance: Alcohol: 1 Caffeine: 5 Cannabis: 2 PCP, other hallucinogens: 2 Inhalant: 2 Opioid: 2, 1 being pupillary constriction Sedative/Hypnotic/Anxiolytic: 1 Stimulant: 2		
Exclusions	Other medical condition Substance- or medication-induced, including withdrawal Other mental disorder	Intoxication due to poisoning	Other physical or mental disorders
Symptom specifiers	**Substance-specific specifiers:** Cannabis intoxication: With perceptual disturbance: hallucinations occurring in the setting of intact reality testing or hallucinations in the absence of delirium Opioid intoxication:		

	With perceptual disturbance: hallucinations occurring in the setting of intact reality testing or hallucinations in the absence of delirium	
Severity specifiers		Mild Moderate Severe

Table 85.
Substance Withdrawal

Diagnostic name	Substance withdrawal ► Alcohol ► Caffeine ► Cannabis ► Opioids ► Sedatives, hypnotics, anxiolytics ► Stimulants ► Tobacco	Mental and behavioral disorders due to the use of (indicate substance)	Substance withdrawal
Duration			Usually, 6–12 hours after last using the substance
Symptoms	Reduction or cessation of use following a pattern of prolonged and/or heavy use Symptoms of substance-specific withdrawal syndrome following cessation or reduction ► ≥2 symptoms of established sedative/hypnotic/anxiolytic withdrawal syndrome within hours to days ► ≥2 symptoms of established alcohol withdrawal syndrome ► Dysphoric mood in addition to ≥2 symptoms of stimulant withdrawal syndrome within hours to days ► ≥3 symptoms of opioid withdrawal syndrome minutes to days ► ≥3 symptoms of caffeine withdrawal within 24 hours ► ≥3 symptoms of cannabis withdrawal syndromes ► ≥4 symptoms of tobacco withdrawal syndrome within 24 hours Withdrawal symptoms cause distress and/or impairment in functioning	Group of symptoms occurring with cessation or reduction of a substance following a period of prolonged and/or regular use Symptoms are time limited and substance-specific	Presence of symptoms, behaviors or physiologic features associated with withdrawal from a particular substance (differs by substance).
Required number of symptoms	All of the above		
Psychosocial consequences	Distress and/or impairment in functioning		
Exclusions	Other medical condition Substance- or medication-induced, including		Other medical condition Other mental disorder

	withdrawal Other mental disorder		
Symptom specifiers	**Substance-specific specifiers:** Alcohol withdrawal: ***With perceptual disturbance:*** hallucinations occurring in the setting of intact reality testing or hallucinations in the absence of delirium Sedative/hypnotic/anxiolytic withdrawal: ***With perceptual disturbance:*** hallucinations occurring in the setting of intact reality testing or hallucinations in the absence of delirium	Withdrawal state with delirium	For alcohol and sedative, hypnotic, or anxiolytic: With perceptual disturbances With seizures

Table 86.
Hallucinogen Persisting Perception Disorder/Hallucinogen-Induced Psychotic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Hallucinogen persisting perception disorder	Posthallucinogen perception disorder	Hallucinogen-induced psychotic disorder
Symptoms	Re-experiencing, following cessation of use, perceptual symptoms that were present during intoxication Symptoms cause distress or functional impairment	Substance-induced changes in cognition, personality, affect, behavior persisting beyond generally accepted period, with onset of symptoms directly related to use of substance Flashbacks are episodic, short duration, and frequently identical or similar to perceptual distortions experienced during acute intoxication	Psychotic symptoms Psychotic symptoms are in excess of that expected for intoxication
Required number of symptoms	Both of the above		
Psychosocial consequences	Distress or psychosocial impairment		Distress or psychosocial impairment
Exclusions	Other medical condition Substance- or medication-induced, including withdrawal Other mental disorder	Alcohol- or psychoactive substance-induced Korsakov syndrome Alcohol- or psychoactive substance-induced psychotic state	Substance- or medication-induced, including withdrawal Other mental disorder

Table 87.
Gambling Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Gambling disorder	Pathologic gambling	Gambling disorder
Duration	Symptoms present within a 12-month period		Extended period
Symptoms	A pattern of problematic gambling behavior, as exhibited by the following: ▶ Need to gamble with higher stakes over time to experience the same level of excitement ▶ Irritability associated with trying to reduce gambling ▶ A pattern of unsuccessful attempts to stop or reduce gambling ▶ Preoccupation with thoughts related to gambling ▶ A pattern of gambling when feeling distressed ▶ A pattern of gambling to make up for prior losses ▶ A pattern of lying to conceal behaviors ▶ Loss of jobs, relationships, or other opportunities due to gambling behaviors ▶ Relies on others for money to fuel gambling	Pattern of gambling that is dominant in the patient's life and resulting in adverse consequences in social, occupational, family, and other areas of life.	Persistent gambling, with ▶ Loss of control over the behavior ▶ Gambling takes precedence over other activities ▶ Continues/escalates despite negative consequences
Required number of symptoms	≥4		All of the above
Psychosocial consequences	Marked impairment and/or distress		Psychosocial or other impairment
Exclusions	Manic episode	Excessive gambling by manic patients Gambling and betting NOS Gambling in dissocial personality disorder	Substance- or medication-induced, including withdrawal Other mental disorder
Symptom specifiers			Predominantly online Predominantly offline
Course specifiers	**Episodic**: intermittently meeting diagnostic criteria at more than one point over a period of		

	time, with periods of disordered gambling separated by ≥ several months **Persistent:** continuous symptoms and meeting diagnostic criteria for several years **In early remission:** no symptoms over a period of 3 months up to 12 months after the initial diagnosis **In sustained remission:** no symptoms over a period of 12 months or longer after the initial diagnosis
Severity specifiers	**Mild:** 4–5 criteria **Moderate:** 6–7criteria **Severe:** 8–9 criteria

Table 88.
Internet Gaming Disorder/Gaming Disorder

	DSM-TR	ICD-11
Diagnostic name	Internet gaming disorder	Gaming disorder
Duration	1 year	Extended period
Symptoms	Preoccupation with online games Withdrawal when games are taken away Tolerance to the activity (needing more time to play) Failed quit attempts Loss of interest in alternative activities Continued use despite insight into gaming as a problem Deceived others about the amount of gaming Use of games to avoid negative moods	Persistent gaming, with ▶ Loss of control over the behavior ▶ Gaming takes precedence over other activities ▶ Continues/escalates despite negative consequences
Required number of symptoms	≥5	All of the above
Psychosocial consequences	Psychosocial impairment: risked or lost relationships, jobs, or other opportunities due to gaming	Psychosocial or other impairment
Exclusions	Gambling games or pornography sites	Substance- or medication-induced, including withdrawal Other mental disorder
Symptom specifiers		Predominantly online Predominantly offline
Severity specifiers	Mild, moderate, or severe, depending on the number of symptoms and amount of psychosocial consequences	
Comment	Included as a proposed diagnosis under “Conditions for Further Study.”	

17. NEUROCOGNITIVE DISORDERS

Table 89.
Major and Mild Neurocognitive Disorders/Dementias

	DSM-5-TR		ICD-10	ICD-11
Diagnostic name	Major and mild neurocognitive disorders		Dementias	Dementia
Symptoms	Significant (**Major**) or moderate (**Minor**) neurocognitive decline from baseline or impairment per neuropsychiatric testing in ≥1 cognitive domains of: ▶ Complex attention ▶ Executive function ▶ Learning and memory ▶ Language ▶ Perceptual-motor ▶ Social cognition			Marked impairment in ≥2 cognitive domains than expected for age and premorbid functioning
Required number of symptoms	See above criteria			
Exclusions	Delirium Other mental disorder			Coma Delirium Disorders of intellectual development Neurodevelopmental disorders Stupor Aging-associated decline in intrinsic capacity
Psychosocial consequences	Some impairments in the ability to independently perform activities of daily living			
Symptom specifiers	**Major/mild neurocognitive disorder due to Alzheimer disease**		**Dementia in Alzheimer disease**	**Dementia due to Alzheimer disease**
	Mild	**Major**		
	Probable: evidence of causative genetic mutation **Possible:** no evidence of genetic mutation in addition to all of the following: ▶ A decline in memory and learning ▶ Progressive decline in cognition without extended plateaus ▶ No evidence of mixed etiology	**Probable:** evidence of genetic mutation present or all three of the following: ▶ A decline in memory/learning in addition to ≥1 other cognitive domain ▶ Progressive decline without extended plateaus ▶ No evidence of a mixed etiology **Possible:** ▶ The above criteria are not met for probable	Dementia in Alzheimer disease with early onset Dementia in Alzheimer disease with late onset Dementia in Alzheimer disease, atypical or mixed type Dementia in Alzheimer disease, unspecified Early onset: < age 65, and symptoms progressing more rapidly and involving multiple higher areas of cognitive functioning Late onset: after age 65, with slower progression and prominent memory deficits Symptoms present with insidious onset and progressive decline over several years and are accompanied by characteristic neuropathology and neurochemical features.	Insidious memory impairment Impairment in an additional cognitive domain May include mental or behavioral symptoms Course specifiers: Dementia due to Alzheimer disease Dementia due to Alzheimer disease with early onset Dementia due to Alzheimer disease with late onset Alzheimer disease dementia, mixed type, with cerebrovascular disease Alzheimer disease dementia, mixed type, with other nonvascular etiologies Dementia due to Alzheimer disease, onset unknown or unspecified Severity specifiers: Mild Moderate Severe

Major/mild frontotemporal neurocognitive disorder		**Dementia in Picks disease** Circumscribed brain atrophy	**Frontotemporal lobar degeneration**
Behavioral variant	**Language variant**		
Spared learning and memory, with a decline in social cognition and/or executive function occurring with ≥3 of the following: ► Disinhibited behavior ► Apathy ► Loss of sympathy/ empathy ► Perseveration or stereotypic behavior ► Hyperorality or dietary changes **Probable:** ► Evidence of possible genetic mutation ► Neuroimaging showing prominent frontal and/or temporal involvement **Possible:** above criteria not met	A decline in language prominent as evidenced by a decline in speech production, word finding, naming, grammar, and/ or comprehension, with relative sparing in learning and memory Probable: ► Evidence of possible genetic mutation ► Neuroimaging showing prominent frontal and/or temporal involvement Possible: The above criteria are not met	Progressive dementia, often beginning in middle age, involving changes in personality and social skills, with the eventual development of deficits in memory, mood, and neurologic function.	Frontotemporal dementia Personally changes (apathy, inappropriate social behavior) Relatively preserved neurocognitive functioning during early stages Variants: Behavioral variant: personality changes, usually apathy and inappropriate social behavior, predominate and usually precede other cognitive changes. Primary progressive aphasia: affects language skills first Motoric variant: progressive motor impairment, with attention, executive functioning, and visuospatial functioning usually affected before memory. Severity specifiers: Mild Moderate Severe
Major or mild neurocognitive disorder with Lewy bodies		**Dementia in other specified diseases classified elsewhere**	**Lewy body disease**
Mild	**Major**		
Core features: ► Fluctuation in cognition with significant variation in attention/alertness ► Recurrent well-formed visual hallucinations ► Parkinsonian symptoms presenting after cognitive decline Suggestive features: ► REM sleep behavior disorder ► Severe neuroleptic sensitivity **Probable:** the presence of two core features or one suggestive feature with ≥1 core feature **Possible:** one of the above three core features present			Dementia due to Lewy body disease Recurrent visual hallucinations Episodic confusion REM sleep behavioral disorder Parkinsonian symptoms Neurocognitive symptoms are progressive and usually affect visuospatial skills, attention, and executive functioning more than memory. Severity specifiers: Mild Moderate Severe
Major or mild vascular neurocognitive disorder		**Vascular dementia**	**Dementia due to cerebrovascular disease**
Mild	**Major**		
In addition to history, imaging, or physical findings consistent with cerebrovascular disease, there is cognitive decline with a pattern suggestive of vascular etiology, as evidenced by ≥1 of the following: ► Cognitive deficits temporally related to cerebrovascular events ► Decline predominantly in complex attention and frontal-executive function **Probable:** ≥1 of the following present ► Neuroimaging showing significant parenchymal injury due to cerebrovascular disease ► Neurocognitive symptoms correlate with documented cerebrovascular events ► Clinical and genetic evidence of cerebrovascular disease present **Possible:** ► No neuroimaging and no documented temporal relationship of cerebrovascular events to cognitive decline are available		**Vascular dementia of acute onset** (symptoms develop after multiple strokes or a single severe stroke) **Multi-infarct dementia** (progressive symptoms following multiple transient ischemic episodes and accumulating infarcts) **Subcortical vascular dementia** (associated with a history of hypertension and foci of injury in white matter, with relatively preserved cerebral cortex) **Mixed cortical and subcortical vascular dementia** **Other vascular dementia** **Vascular dementia, unspecified**	Deficits in: Information processing Complex attention Frontal-executive functioning Evidence of cerebrovascular disease

Major or mild neurocognitive disorder due to traumatic brain injury			**Dementia due to injury to the head**
Mild	**Major**		
Noncognitive symptoms exist in conjunction with a history of traumatic brain injury (symptoms occurring immediately after injury and persisting past the acute period), with ≥1 of the following present: ▶ Loss of consciousness ▶ Post-traumatic amnesia ▶ Disorientation and confusion ▶ Neurologic symptoms or injury on neuroimaging			Symptoms arrive immediately following head trauma or after the individual gains consciousness. Persists beyond acute postinjury period. Cognitive symptoms vary depending on the location of the injury.
Major or mild neurocognitive disorder due to HIV infection		**Dementia in human immunodeficiency virus (HIV)**	**Dementia due to diseases classified elsewhere**
Mild	**Major**		
Neurocognitive symptoms occurring in the presence of HIV diagnosis		Cognitive symptoms developing in the context of known HIV diagnosis	Dementia due to human immunodeficiency virus Confirmed HIV disease No other illness present to explain neurocognitive symptoms Typically subcortical symptoms predominate
Substance/medication-induced major or mild neurocognitive disorder		**Mental and behavioral disorders due to psychoactive substance use**	**Dementia due to psychoactive substances including medications**
Mild	**Major**		
Alcohol ▶ Inhalant ▶ Sedative, hypnotic, or anxiolytic ▶ Other (or unknown)	Alcohol, nonamnestic confabulatory type Alcohol, amnestic confabulatory type Inhalant Sedative, hypnotic, or anxiolytic Other (or known)	Amnesic syndrome Residual and late-onset psychotic disorder	Any dementia that is a direct consequence of substance use Exclusion: dementia due to heavy metals or other toxins
Symptoms of cognitive impairment, occurring not solely in the period of intoxication and/or withdrawal that remain present after a period of abstinence **Persistent:** symptoms remain present after an extended period of abstinence			
Major or mild neurocognitive disorder due to Prion disease		**Dementia in Creutzfeldt–Jakob disease**	**Dementia due to prion disease**
Mild	**Major**		
Symptoms of cognitive impairment, with insidious onset and rapid progression of deficits; symptoms accompanied by motor features (myoclonus, ataxia) or biochemical marker on testing.		Dementia with significant neurologic symptoms, often with a subacute course and progressive rapid decline.	Insidious and rapid onset of symptoms, including cognitive deficits, ataxia, and motor symptoms. Confirmed by brain imaging and spinal fluid or genetic testing. EEG may also support this.
Major or mild neurocognitive disorder due to Parkinson disease		**F02.3 Dementia in Parkinson disease**	
Mild	**Major**		
Neurocognitive symptoms occurring in the context of known Parkinson disease diagnosis, frequently involving insidious onset and gradual progression **Probable** (both of the following met) **Possible** (one of the following met) ▶ No evidence of mixed etiology ▶ Parkinson disease precedes the onset of neurocognitive disorder		Dementia occurring in the context of Parkinson disease.	

	Major or mild neurocognitive disorder due to Huntington disease		**Huntington disease**	**Dementia due to Huntington disease**
	Mild	Major		
	Neurocognitive symptoms occurring in the context of known Huntington disease diagnosis, frequently involving insidious onset and gradual progression		Dementia occurs as a result of diffuse degeneration in the brain related to Huntington disease, caused by an autosomal dominant gene; the disease has slow progression and often involves associated motor symptoms of chorea.	Insidious symptoms in the 30s or 40s, with gradual/slow progression. Typically executive impairments predominate over memory ≥ before motor symptoms (bradykinesia, chorea) begin.
	Major or mild neurocognitive disorder due to another medical condition			
	Major or mild neurocognitive disorder due to multiple etiologies			
	Unspecified neurocognitive disorder			
Severity specifiers	**Mild:** impairments in more complex activities of daily living (i.e., money management) **Moderate:** impairment in basic activities of daily living (i.e., eating, dressing) **Severe:** fully dependent on others for all daily activities			
				Other diagnoses included in ICD-11: Dementia due to Parkinson disease Dementia due to exposure to heavy metals and other toxins Dementia due to multiple sclerosis Dementia due to normal pressure hydrocephalus Dementia due to pellagra Dementia due to Down syndrome
Additional symptom specifiers (common to all)	**With or without behavioral disturbance**			

Table 90.
Delirium

	DSM-5-TR	**ICD-10**	**ICD-11**
Diagnostic name	Delirium	Delirium, not induced by alcohol and other psychoactive substances Delirium not superimposed on dementia Delirium superimposed on dementia Other delirium Delirium, unspecified	Delirium
Symptoms	Disturbance in attention and awareness Symptoms develop acutely, represent a change from baseline, and may fluctuate Additional disturbance in cognitive function, memory, language, orientation, and/or perception History, physical exam, labs, or imaging indicative of the physiologic cause of cognitive disturbance	Nonspecific organic cognitive syndrome with disturbed consciousness, awareness, memory, motor function, sleep, and emotion, with a variable duration and severity; it can be acute or subacute	Disturbance of attention, orientation, and awareness Develops quickly Change from baseline functioning It can present as confusion or global neurocognitive impairment May fluctuate Often includes behavioral and emotional disturbances May include disturbance of the sleep/wake cycle
Required number of symptoms	All of the above		
Exclusions	Neurocognitive disorder Reduced arousal (i.e., coma)		Result of: ▸ Neurocognitive disorder ▸ Another mental disorder ▸ Substance intoxication
Symptom specifiers	Substance intoxication delirium, with (mild, mod, or severe) or without use disorder Substance withdrawal delirium, with (mild, mod, or severe) or without use disorder Medication-induced delirium Delirium due to another medical condition Delirium due to multiple etiologies Hyperactive Hypoactive		Delirium due to disease classified elsewhere Delirium due to psychoactive substances including medications Delirium due to multiple etiologic factors Delirium, other specified cause Delirium, unspecified or unknown cause

	Mixed level of activity	
Course specifiers	**Acute** (lasting hours to days) **Persistent** (lasting weeks to months)	
Comments		If due to substance use, use “Mental and behavioral disorders due to psychoactive substances”

18. PERSONALITY DISORDERS

Table 91.
General Personality Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	General personality disorder	Disorders of adult personality and behavior	Personality disorder
Duration	Long duration of time, beginning ≥ in adolescence or early adulthood		≥2 years, tends to begin in childhood
Symptoms	A fixed and pervasive pattern of experience and behavior, as manifested in: ▶ Cognition and perception ▶ Affect ▶ Interpersonal functioning ▶ Impulsivity	Includes a variety of patterns of behavior that are persistent and involve a clinical disturbance in interpersonal relationships and views of self. These patterns of behavior and experience are fixed and result in inflexibility	Problems in function in aspects of the self or interpersonal dysfunction Patterns of cognition, emotional experience and expression, and maladaptive behaviors Disturbance occurs in a range of personal/social situations, although certain situations may provoke
Required number of symptoms	≥2 of the above being long-standing and present across a range of social situations		
Exclusions	Other medical condition Substance- or medication-induced, including withdrawal Other mental disorder		Other medical/nervous system conditions Substance- or medication-induced, including withdrawal Other mental disorder Developmentally appropriate behavior
Psychosocial consequences	Distress or psychosocial impairment	Frequently (but not always) associated with distress and difficulties with social performance	
Symptom specifiers			Categorized by traits or patterns: **Negative affectivity in personality disorder or personality difficulty:** tendency to experience a broad range of negative emotions. **Detachment in personality disorder or personality difficulty:** a tendency

to maintain interpersonal and emotional distance.

Dissociality in personality disorder or personality difficulty: disregard for rights and feelings of others. Self-centered and lacking empathy.

Disinhibition in personality disorder or personality difficulty: acts rashly and impulsively, without consideration of consequences.

Anankastia in personality disorder or personality difficulty: having a rigid focus, commonly manifested by perfectionism and emotional and behavioral constraint.

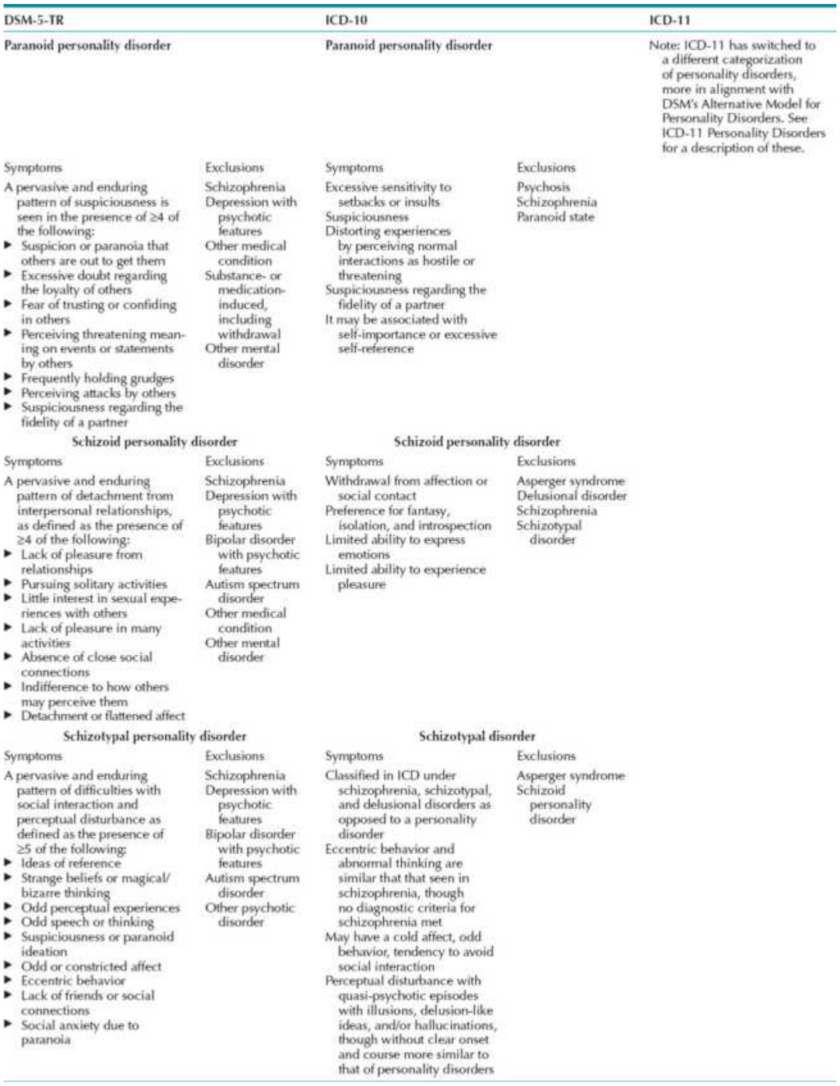
Borderline pattern: included as an additional specifier, which typically overlaps with the above specifiers. This is meant to indicate a pervasive pattern of instability in interpersonal relationships, self-image, emotions, and a tendency toward impulsivity.

Symptoms include ≥5 of the following:

- Avoidance of abandonment
- Unstable and intense interpersonal relationships
- Identity disturbance
- Acting rashly, often with risky activities (sexual behavior, driving, drinking, or eating)

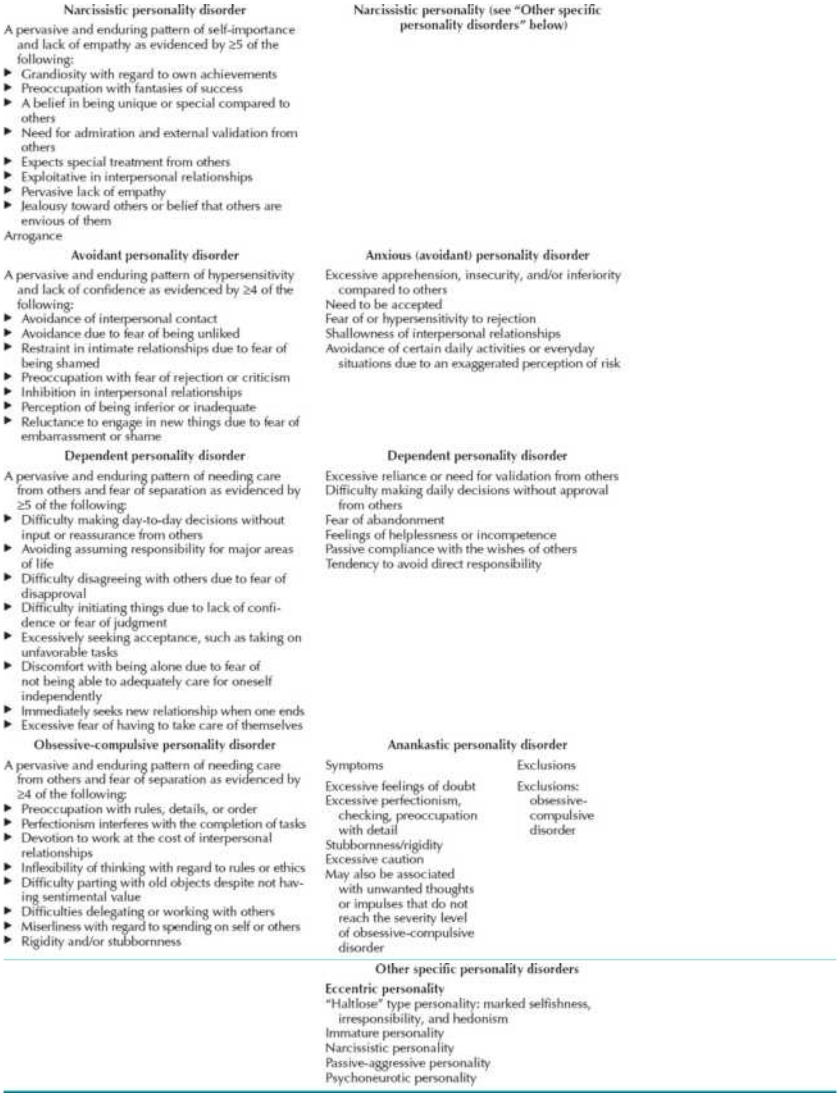
			▶ Self-harm ▶ Emotional instability ▶ Feeling empty inside ▶ Difficulty controlling anger ▶ Transient dissociative episodes
Severity specifiers			Severity depends on the range of areas affected
Comments	Includes: **Cluster A:** paranoid personality disorder, schizoid personality disorder, schizotypal personality disorder **Cluster B:** antisocial personality disorder, borderline personality disorder, histrionic personality disorder, narcissistic personality disorder **Cluster C:** avoidant personality disorder, dependent personality disorder, obsessive-compulsive personality disorder	Includes: **Specific personality disorders:** Paranoid personality disorder, schizoid personality disorder, dissocial personality disorder, emotionally unstable personality disorder, histrionic personality disorder, anankastic personality disorder, anxious (avoidant) personality disorder, dependent personality disorder, other specific personality disorders (eccentric, haltlose, immature, narcissistic, passive-aggressive, psychoneurotic), personality disorder unspecified **Mixed and other personality disorders** **Enduring personality changes:** due to brain damage and disease, after a catastrophic experience, after psychiatric illness, chronic pain personality syndrome, enduring personality change unspecified	

Table 92.
Specific Symptoms and Exclusions for Individual Personality Disorders



DSM-5-TR		ICD-10		ICD-11
Paranoid personality disorder		**Paranoid personality disorder**		Note: ICD-11 has switched to a different categorization of personality disorders, more in alignment with DSM's Alternative Model for Personality Disorders. See ICD-11 Personality Disorders for a description of these.
Symptoms	Exclusions	Symptoms	Exclusions	
A pervasive and enduring pattern of suspiciousness is seen in the presence of ≥4 of the following: ▶ Suspicion or paranoia that others are out to get them ▶ Excessive doubt regarding the loyalty of others ▶ Fear of trusting or confiding in others ▶ Perceiving threatening meaning on events or statements by others ▶ Frequently holding grudges ▶ Perceiving attacks by others ▶ Suspiciousness regarding the fidelity of a partner	Schizophrenia Depression with psychotic features Other medical condition Substance- or medication-induced, including withdrawal Other mental disorder	Excessive sensitivity to setbacks or insults Suspiciousness Distorting experiences by perceiving normal interactions as hostile or threatening Suspiciousness regarding the fidelity of a partner It may be associated with self-importance or excessive self-reference	Psychosis Schizophrenia Paranoid state	
Schizoid personality disorder		**Schizoid personality disorder**		
Symptoms	Exclusions	Symptoms	Exclusions	
A pervasive and enduring pattern of detachment from interpersonal relationships, as defined as the presence of ≥4 of the following: ▶ Lack of pleasure from relationships ▶ Pursuing solitary activities ▶ Little interest in sexual experiences with others ▶ Lack of pleasure in many activities ▶ Absence of close social connections ▶ Indifference to how others may perceive them ▶ Detachment or flattened affect	Schizophrenia Depression with psychotic features Bipolar disorder with psychotic features Autism spectrum disorder Other medical condition Other mental disorder	Withdrawal from affection or social contact Preference for fantasy, isolation, and introspection Limited ability to express emotions Limited ability to experience pleasure	Asperger syndrome Delusional disorder Schizophrenia Schizotypal disorder	
Schizotypal personality disorder		**Schizotypal disorder**		
Symptoms	Exclusions	Symptoms	Exclusions	
A pervasive and enduring pattern of difficulties with social interaction and perceptual disturbance as defined as the presence of ≥5 of the following: ▶ Ideas of reference ▶ Strange beliefs or magical/bizarre thinking ▶ Odd perceptual experiences ▶ Odd speech or thinking ▶ Suspiciousness or paranoid ideation ▶ Odd or constricted affect ▶ Eccentric behavior ▶ Lack of friends or social connections ▶ Social anxiety due to paranoia	Schizophrenia Depression with psychotic features Bipolar disorder with psychotic features Autism spectrum disorder Other psychotic disorder	Classified in ICD under schizophrenia, schizotypal, and delusional disorders as opposed to a personality disorder Eccentric behavior and abnormal thinking are similar that that seen in schizophrenia, though no diagnostic criteria for schizophrenia met May have a cold affect, odd behavior, tendency to avoid social interaction Perceptual disturbance with quasi-psychotic episodes with illusions, delusion-like ideas, and/or hallucinations, though without clear onset and course more similar to that of personality disorders	Asperger syndrome Schizoid personality disorder	

Antisocial personality disorder		**Dissocial personality disorder**	
Symptoms	Exclusions	Symptoms	Exclusions
The pervasive and enduring presence of ≥3 of the following, occurring since the age of 15 and diagnosed no earlier than the age of 18, with evidence of conduct disorder before the age of 15: ▶ Not following social norms with regard to the law ▶ A pattern of deceitfulness and lying ▶ Impulsivity ▶ Irritability and/or aggressiveness ▶ Blatant disregard for the safety of self or others ▶ Irresponsibility with regard to work, social, and personal obligations ▶ Lack of remorse	Schizophrenia Bipolar disorder	Disregard for social expectations or obligations Lack of concern for the feelings of others Behaviors starkly different from those expected per social norms Low distress/frustration tolerance Low threshold for aggression or violence Tendency to blame others	Conduct disorders Emotionally unstable personality disorder
Borderline personality disorder		**Emotionally unstable personality disorder**	
Symptoms		Symptoms	Exclusions
A pervasive and enduring pattern of interpersonal conflict and impulsivity as evidenced by ≥5 of the following: ▶ An excessive effort to avoid real or feared abandonment ▶ Unstable and frequently intense interpersonal relationships, with a pattern of alternating between idealization and devaluation ▶ Unstable image of self ▶ Impulsivity resulting in self-harm ▶ Pattern of suicidal behaviors, gestures, threats, or self-injury ▶ Affective lability ▶ Chronic feelings of emptiness ▶ Difficulties managing anger ▶ Intermittent stress-related paranoia and/or feelings of dissociation		Tendency to impulsiveness Unpredictable and labile mood Behavioral and/or emotional outbursts are common Frequent conflict with others Two distinct "Types" include: ▶ Impulsive type (emotional lability and lack of impulse control) ▶ Borderline type (disturbance of self-image, self-worth, and interpersonal relationships, with associated self-destructive behavior)	Dissocial personality disorder
Histrionic personality disorder		**Histrionic personality disorder**	
A pervasive and enduring pattern of needing attention and experiencing strong emotions as evidenced by ≥5 of the following: ▶ Discomfort in situations in which the individual is not the main object of attention ▶ Excessively sexual or provocative behavior in interpersonal interaction ▶ Labile emotions ▶ Use of physical appearance to draw attention ▶ Impressionistic style of speech ▶ Exaggerated expressions and speech ▶ High suggestibility ▶ Perceives relationships as being more intimate than they actually are		Shallow and labile affect Self-dramatization Exaggeration of speech and affect Suggestibility Egocentricity Lack of concern for others Attention seeking Easily offended or hurt emotionally	



Narcissistic personality disorder A pervasive and enduring pattern of self-importance and lack of empathy as evidenced by ≥5 of the following: ▶ Grandiosity with regard to own achievements ▶ Preoccupation with fantasies of success ▶ A belief in being unique or special compared to others ▶ Need for admiration and external validation from others ▶ Expects special treatment from others ▶ Exploitative in interpersonal relationships ▶ Pervasive lack of empathy ▶ Jealousy toward others or belief that others are envious of them Arrogance	**Narcissistic personality (see "Other specific personality disorders" below)**
Avoidant personality disorder A pervasive and enduring pattern of hypersensitivity and lack of confidence as evidenced by ≥4 of the following: ▶ Avoidance of interpersonal contact ▶ Avoidance due to fear of being unliked ▶ Restraint in intimate relationships due to fear of being shamed ▶ Preoccupation with fear of rejection or criticism ▶ Inhibition in interpersonal relationships ▶ Perception of being inferior or inadequate ▶ Reluctance to engage in new things due to fear of embarrassment or shame	**Anxious (avoidant) personality disorder** Excessive apprehension, insecurity, and/or inferiority compared to others Need to be accepted Fear of or hypersensitivity to rejection Shallowness of interpersonal relationships Avoidance of certain daily activities or everyday situations due to an exaggerated perception of risk
Dependent personality disorder A pervasive and enduring pattern of needing care from others and fear of separation as evidenced by ≥5 of the following: ▶ Difficulty making day-to-day decisions without input or reassurance from others ▶ Avoiding assuming responsibility for major areas of life ▶ Difficulty disagreeing with others due to fear of disapproval ▶ Difficulty initiating things due to lack of confidence or fear of judgment ▶ Excessively seeking acceptance, such as taking on unfavorable tasks ▶ Discomfort with being alone due to fear of not being able to adequately care for oneself independently ▶ Immediately seeks new relationship when one ends ▶ Excessive fear of having to take care of themselves	**Dependent personality disorder** Excessive reliance or need for validation from others Difficulty making daily decisions without approval from others Fear of abandonment Feelings of helplessness or incompetence Passive compliance with the wishes of others Tendency to avoid direct responsibility
Obsessive-compulsive personality disorder A pervasive and enduring pattern of needing care from others and fear of separation as evidenced by ≥4 of the following: ▶ Preoccupation with rules, details, or order ▶ Perfectionism interferes with the completion of tasks ▶ Devotion to work at the cost of interpersonal relationships ▶ Inflexibility of thinking with regard to rules or ethics ▶ Difficulty parting with old objects despite not having sentimental value ▶ Difficulties delegating or working with others ▶ Miserliness with regard to spending on self or others ▶ Rigidity and/or stubbornness	**Anankastic personality disorder** Symptoms Excessive feelings of doubt Excessive perfectionism, checking, preoccupation with detail Stubbornness/rigidity Excessive caution May also be associated with unwanted thoughts or impulses that do not reach the severity level of obsessive-compulsive disorder Exclusions Exclusions: obsessive-compulsive disorder
	Other specific personality disorders **Eccentric personality** "Haltlose" type personality: marked selfishness, irresponsibility, and hedonism Immature personality Narcissistic personality Passive-aggressive personality Psychoneurotic personality

19. PARAPHILIC DISORDERS

Table 93.
Voyeuristic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Voyeuristic disorder	Voyeurism	Voyeuristic disorder
Duration	6 months or longer		
Symptoms	Sexual arousal, sexual fantasies, sexual urges resulting from observing an unknowing person undressing or engaging in sexual activity The individual must be 18 years or older at the time of diagnosis	A pattern of watching people engage in sexual behaviors or other intimate behaviors, such as undressing, with the individual experiencing sexual pleasure from the experience; those being observed are often not aware	Sustained focus and pattern or arousal from observing an unsuspecting person naked or disrobing Has acted on these thoughts or been distressed by them
Exclusions			Children or (usually) adolescents Single or limited instances
Psychosocial consequences	Distress or psychosocial impairment		
Symptom specifiers	***In a controlled environment (if the individual lives in an institution or other controlled environment)***		
Course specifiers	**In full remission** (no action on urges and no related distress or impairment over ≥5 years while in a noncontrolled environment)		

Table 94.
Exhibitionistic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Exhibitionistic disorder	Exhibitionism	Exhibitionistic disorder
Duration	6 months or longer		
Symptoms	Sexual arousal, sexual fantasies, sexual urges, and sexual behaviors resulting from the act of exposing one's genitals to unsuspecting individuals	A pattern of exposing genitals to strangers, often of the opposite sex, or exposing genitals in public places; such exposure is frequently associated with sexual excitement/arousal and may be followed by masturbation.	Sustained and focused pattern or arousal from exposing one's genitals to unsuspecting person in public Has acted on these thoughts or been distressed by them
Exclusions			Children or (usually) adolescents Single or limited instances
Psychosocial consequences	Distress or psychosocial impairment		
Symptom specifiers	**Sexually aroused by exposing genitals to prepubertal children** Sexually aroused by exposing genitals to physically mature individuals Sexually aroused by exposing genitals to prepubertal children and to physically mature individuals **In a controlled environment** (if the individual lives in an institution or other controlled environment)		
Course specifiers	**In full remission** (no action on urges and no related distress or impairment over ≥5 years while in a noncontrolled environment)		

Table 95.
Frotteuristic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Frotteuristic disorder	Other disorders of sexual preference ***Frotteurism***	Frotteuristic disorder
Duration	6 months or longer		
Symptoms	Sexual arousal, sexual fantasies, sexual urges, and sexual behaviors resulting from touching or rubbing against a nonconsenting individual	Sexual arousal through rubbing against people in public spaces	Sustained and focused pattern or arousal from touching or rubbing against a nonconsenting person Has acted on these thoughts or been distressed by them
Exclusions			Children or (usually) adolescents Single or limited instances
Psychosocial consequences	Distress or psychosocial impairment		
Symptom specifiers	**In a controlled environment** (if the individual lives in an institution or other controlled environment)		
Course specifiers	**In full remission** (no action on urges and no related distress or impairment over ≥5 years while in a noncontrolled environment)		
Comments		Also includes ***Necrophilia,*** in addition to behaviors such as making obscene phone calls, engaging in sexual activity with animals, and use of strangulation for sexual excitement	

Table 96.
Sexual Masochism Disorder/Sadomasochism

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Sexual masochism disorder	Sadomasochism	Paraphilic disorder involving solitary behavior or consenting individuals
Duration	6 months or longer		
Symptoms	Sexual arousal, sexual fantasies, and sexual urges resulting from being humiliated, hit, bound, or made to suffer.	Preference for sexual activity to include bondage or the infliction of pain or humiliation as the recipient (masochism) or as the one inflicting on another (sadism), with associated sexual excitement	General category for a pattern or atypical sexual arousal Causes distress and significant risk of injury
Psychosocial consequences	Distress or psychosocial impairment		Marked distress
Symptom specifiers	**With asphyxiophilia** (sexual arousal related to restriction of breathing) **In a controlled environment** (if the individual lives in an institution or other controlled environment)		
Course specifiers	**In full remission** (no action on urges and no related distress or impairment over ≥5 years while in a noncontrolled environment)		

Table 97.
Sexual Sadism Disorder/Sadomasochism

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Sexual sadism disorder	Sadomasochism	Coercive sexual sadism disorder
Duration	6 months or longer		
Symptoms	Sexual arousal, sexual fantasies, and sexual urges resulting from inflicting psychological suffering or humiliation on others.	Preference for sexual activity to include bondage or the infliction of pain or humiliation as the recipient (masochism) or as the one inflicting on another (sadism), with associated sexual excitement	Sustained and focused pattern or arousal from inflicting physical/psychological suffering on a nonconsenting person Has acted on these thoughts or been distressed by them
Exclusions			Children or (usually) adolescents Single or limited instances
Symptom specifiers	**In a controlled environment** (if the individual lives in an institution or other controlled environment)		
Course specifiers	**In full remission** (no action on urges and no related distress or impairment over ≥5 years while in a noncontrolled environment)		

Table 98.
Pedophilic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Pedophilic disorder	Pedophilia	Pedophilic disorder
Duration	6 months or longer		
Symptoms	Sexual arousal, sexual fantasies, sexual urges, and sexual behaviors involving sexual activity with prepubescent child or children Individual must be 16 years or older at the time of diagnosis and must also be a minimum of 5 years older than the child of sexual interest	Sexually preferring young boys and girls, often those of prepubertal or early pubertal age	Sustained and focused pattern or arousal from prepubertal children Has acted on these thoughts or been distressed by them
Required number of symptoms	Both of the above		
Exclusions	Individual of adolescent age in a relationship with another child aged 12 or 13		Children or (usually) adolescents Single or limited instances Cultural variations in acceptable behavior
Psychosocial consequences	Distress or psychosocial impairment		
Symptom specifiers	**Exclusive type:** attracted only to children Nonexclusive type Sexually attracted to males Sexually attracted to females Sexually attracted to both males and females Limited to incest		

Table 99.
Fetishistic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Fetishistic disorder	Fetishism	Paraphilic disorder involving solitary behavior or consenting individuals
Duration	≥6 months		
Symptoms	Sexual arousal, sexual fantasies, sexual urges, and sexual behaviors resulting from inanimate objects or a highly specific nongenital body part	Using nonliving objects as a source of sexual arousal or gratification or a way to enhance sexual excitement.	General category for a pattern or atypical sexual arousal. Causes distress and significant risk of injury.
Exclusions	Limited to: ▸ Clothing related to cross-dressing (transvestic disorder) ▸ Use of devices related to genital stimulation		
Psychosocial consequences			Marked distress
Symptom specifiers	Body part(s) Nonliving object(s) Other **In a controlled environment** (if the individual lives in an institution or other controlled environment)		
Course specifiers	**In full remission** (no action on urges and no related distress or impairment over ≥5 years while in a noncontrolled environment)		

Table 100.
Transvestic Disorder

	DSM-5-TR	ICD-10	ICD-11
Diagnostic name	Transvestic disorder	Dual-role transvestism Fetishistic transvestism	Paraphilic disorder involving solitary behavior or consenting individuals
Duration	6 months or longer		
Symptoms	Sexual arousal, sexual fantasies, and sexual urges resulting from cross-dressing	***Dual role:*** enjoyment associated with temporarily wearing clothes of the opposite sex, but without associated sexual excitement or associated desire for permanent sex change ***Fetishistic:*** wearing clothes of the opposite sex associated with sexual excitement and desire to remove clothing once orgasm occurs and arousal declines	General category for a pattern or atypical sexual arousal. Causes distress and significant risk of injury
Psychosocial consequences	Distress or psychosocial impairment		Marked distress
Symptom specifiers	**With fetishism:** sexual arousal from specific fabrics or garments) **With autogynephilia:** sexual arousal from imagining self as a female **In a controlled environment:** if the individual lives in an institution or other controlled environment		
Course specifiers	**In full remission:** no action on urges and no related distress/impairment ≥5 years while in a noncontrolled environment
